THE METHODOLOGY OF CLINICAL SCIENCE *

Sir JAMES SPENCE
M.C. M.D Hon LL.D Hon. D.Sc Durh, F R C P
ESSOR OF CHILD HEALTH IN THE UNIVERSITY OF DURHAM

HERE IS a risk in generalising from the few facts which pprehend in our personal experience and I take this in saying that there are two main kinds of clinical ce, of which one is in danger of being overwhelmed he other Out of this distinction I shall try to create ubstance of this lecture

nical science is the planned study of disease, or of phenomena of disease, in men and women and ren who are sick It is a practical craft and this ies that the clinical scientist must possess the cular skills necessary for collecting and systematising nowledge He must possess also the opportunity to is work with such regularity and method as the sion demands. Working within the responsibility he medical care of the patient, he must do nothing h is harmful to his patient or which delays his cure s researches lead the clinical scientist to do more this, or less than this his intentions must be oved by the patient after full explanation of what store for him Approval by the patient will always nfluenced by the attitude and the opinion of the stigator and there can be no tribunal to pass judg t on what is practice and what is malpractice in the tigation of sick patients. Under these circumstances rch methods can be sanctioned *only by that faculty* h distinguishes right from wrong and which we may call conscience. This understanding of what is right what is wrong in the care of patients is part of the ssional knowledge gained in medical schools and hing hospitals from teachers, who hold their teaching for the very reason that they can transmit this ledge, with other knowledge to their assistants and nts

eturn to the two kinds of clinical science One way proach to a definition is to look at their aims The of one kind of clinical science is to know disease in a way as to enable us to infer its cause and to ct its course Seen in this way a disease is regarded equence of phenomena in a sick person arising from following on a noxious injury; and this is in accord the Aristotelian idea of the nature of things The odology of this kind of clinical science is the planned rvation of the sequence of phenomena in that er of sick people which allows us to know the non course of the disease under study from its ning to its end and to estimate and know the tions from that course. Planned observation implies use of all practicable and necessary machines of urement The knowledge it leads to has immense ical values, for to know disease in this way is the of exact therapy in professional practice. This of work might be called clinical cartography use it helps the practitioner to know where he is where he should go

e other kind of clinical science might be called al phenomenology It studies the phenomena of se or of disordered function and its aim is to explain mechanisms and their clinical significance It is rned with auricular fibrillation hunger pain, itchy or hyperpotassaemia, rather than with the diseases hich these phenomena arise. Its methodology starts identification of the phenomena and then goes on e use of experiment when possible and necessary Great benefits have come to both the science and practice of medicine by these detailed analytical studies of clinical phenomena. The knowledge gained has both increased our understanding of old diseases and pointed the way to the discovery of new diseases

Thomas Lewis did so much to establish this precise and rational study of clinical phenomena that it is tempting to use his name as an eponymous title for this kind of clinical research but Lewis's view of medicine went far beyond detailed studies of phenomena, and for that reason I have suggested that if a name has to be found it would be better to call it clinical phenomenology Thomas Lewis, however by the mere force of his personality has so influenced clinical research in this country in recent years that the study of clinical phenomena or 'states of disease' as he called them overshadows other kinds of clinical research The advantages derived from this influence have been enormous but there are grounds for believing that its dominance has led to the neglect of the planned study of disease

Clinical Observation

Before I go further I must try to make clear the different kinds of clinical observation That the instruments of clinical observation are now so disconcertingly numerous makes this all the more necessary We should keep in mind, however, that it is the essence of clinical research that while the observer should know what to look for, he should not be too absorbed to notice the unusual To grasp the significance of the unusual is an uncommon quality, and F M R Walshe stressed this idea in saying:

> It takes the exceptional mind to pass beyond the first exercises of the discriminatory tendency to pick up a hitherto unrecorded phenomenon and to grasp its significance Indeed, many a competent clinician may live out his professional existence never having made a truly original observation.

With this chastening thought in our minds we can try to separate clinical observation into its parts.

There are three main types of clinical observation, and each is as much an expression of a natural cast of mind as of a trained method of approach which is not to say that they cannot all be combined occasionally in one person's skill. How occasionally I cannot estimate for I cannot recollect having seen such a person

The first type of observation is the episodic recognition of spontaneously occurring signs of disease which we use when we diagnose and prognosticate It is the craftsman skill in seeing quickly what he knows to be significant and, as such, it grows out of experience Not all are capable of it to an excellent degree It comes best to those who talk least, and the ebullient loquacious teacher rarely possesses it. It sees the rose spot and the scabies burrow It hears the cry indicating a retropharyngeal abscess, and the wheeze of tracheal pressure. It knows when to dismiss the record of a high blood urea as a laboratory mistake or as an error in collecting the blood into a contaminated tube In its best form it works towards an economy of effort, and has its eye on what is true and what is false in new machines To this practical skill of the experienced clinical observer it is customary to give the name of clinical intuition but if this implies a kind of mystical guessing it no more deserves the name than does the skill of knowing where to find a plover's nest. It is the product not of guessing but of a sifted experience by which the significant is recognised with such rapidity that the steps of reasoning are not discernible to the uninitiated There is, of course and all too commonly, such a thing as clinical guessing, which we may suspect when we hear it bolstered up by expressions of opinion beginning with the words In my experience ' but this does not come into any of

---

ecture to the British Postgraduate Medical Federation, University of London, delivered at the Postgraduate Medical School of London on Jan. 6, 1953

6787

the categories of serious clinical observations we are discussing

This episodic or incidental type of clinical observation is not in itself a method of research It is the tool of professional practice However skilfully it may be used, it is not likely to lead either to discovery or to a decisive clarification of existing knowledge, both of which are the objects of research The truth of this will be known to those who have used the routine clinical notes of hospitals in seeking recorded facts and observations These records may have their value as a teaching instrument, but as instruments of clinical research the routine ward notes and the machinery of hospital records are almost useless

The second type of clinical observation is so rare that I may not make it evident except in examples It comes only to the mind prepared It is Coleridge's "ascertaining vision" which comes to a few "who even in the level streams have detected elements which neither the vale itself or the surrounding mountains contained or could supply" Its essence is the recognition of a new phenomenon or of a new correlation between two previously recognised phenomena Coming to those with a sufficient technical experience, it takes shape only in the minds of those endowed with imagination and insight It is near to the artist's power to see something fresh in "things we have passed a thousand times nor cared to see," but it has been an attribute also of most of the great scientists To describe it I will mention only the example of N M Gregg's brilliant recognition of the association between rubella in the pregnant woman at her eighth to tenth week of pregnancy and the congenital deformities in the child who will be born seven months later If Gregg had not systematised his observations quickly at that time, and in those circumstances, the chance might not have come again or for another hundred years or more It was fortunate that the chance came to the sensitive mind This kind of clinical observation, for which I can find no suitable name, is one of the most scintillating starting points of scientific research But we cannot order it or command it The best we can do is to recognise its possibility in the sensitive few, and to prevent its inhibition by too much teaching, its submersion by too much dogma, and its extinction by too much ritual even though it be the ritual of research

The third kind of clinical observation is what we seek to cultivate in clinical research It is clinical observation planned to answer a carefully prepared question The plan is controlled by well known criteria (*a*) that the question is worth answering, (*b*) that it has not already been answered by someone else, (*c*) that a plan of observation can be designed which is likely to provide an answer to the question, and (*d*) that the observer is the sort of man who will carry out the plan This kind of planned observation is one of the established methods of clinical research, and its scientific value is judged by the design of the plan Its purpose is to discover something, or to clarify some already existing field of knowledge In clinical medicine the latter is not less important than the former, for growth of knowledge is not inevitable, and there is, I think, such a thing as a constant growth of ignorance in medicine, which can be kept in check only by opposing to it the clarifying process of research into the validity of existing knowledge

Examples of planned clinical observation appear in various forms, but I choose the investigation of the outbreak in 1948–49 of poliomyelitis in Canadian Eskimoes at the Chesterfield Inlet because it shows how observation may on occasions rise superior to the experimental method If Peart Rhodes and their colleagues had not taken the opportunity to plan and carry out this observation the circumstances might not have occurred again, nor could anyone have designed an experiment to repeat the circumstances Its significance lay in the fact that it was an outbreak of poliomyelitis in a soil community, the like of which, with the adv the aeroplane, we are not likely to see again The p was unique It showed a case incidence of paraly 185 per 1000 of the population, 1 in 20 of the popu died, no children under the age of four years paralysed, and the epidemic reached its heig February with the mean temperature at −31°F was something unparalleled in the recorded epidem of the disease, and the success of the observ depended on the team of five medical men who flew Toronto to the scene of the epidemic and carried plans into effect There are many other examp planned clinical observation, in more obvious fie inquiry such as controlled therapeutic trials and s in prognosis, but the essential features of all a choice of question worth answering, the definitio limitation of what is to be observed, the tr and character of those who will make the observation the arrangements by which the material for obser is collected, or by which observers go to the ma to make their observations

W A Lister's planned observation of the straw naevus in 1938 will serve as a very straightfo example of design and accuracy The opening wo his simple but near perfect paper are worth noting

> "The idea of this investigation arose at a meeting dermatological section of the Royal Society of Medicine, Dr Barber showed an infant who presented a very number of prominent naevi I was struck by the uncer of all those present as to the best line of treatment adopted, and as to what would happen if nothing were (*Lancet*, 1938, i, 1429)

He thereupon designed his observation—which l five years, and comprised 77 patients—by whicl knowledge of the natural history and treatment c naevus has been established

Planned Observation of Disease

In describing planned observation of a disease th a danger that I create for it an artificial category danger is overcome if we assume that in some ci stances the researcher may use more than one tr skill He may for example be both a trained cl observer and a biochemist, or a morbid anatomist the combination rarely exists Precise clinical observ of a disease, carried out to a prearranged plan, tak much time and energy that the observer has little c of being competent in a second technical field

Planned observation of a disease is simplified i noxious agent and the time of the injury are know it is not the rôle of the clinical scientist to stud nature of the noxious agent That work now pro devolves upon the microbiologist, the chemist, physicist, and the pharmacologist Nor is it the r the clinical scientist to be morbid anatomist or e mental pathologist, who sees disease not as the c scientist sees it Their concepts of disease are ess to the progress of knowledge, and medicine could n exist nor advance without them, but it falls t clinical scientist to see disease as the sequence of ph ena in a living being which follows consequentially fr injury, and, in identifying and measuring the pheno results, to create a corpus of exact knowledge whic be applied in the practice of medicine He ma course of the disease by this sequence of pheno subjectively interpreted by the patient and objec identified by himself His main task is to plac phenomena in temporal and in quantitative relatio with each other This leads him to know the cours disease as it may be expected commonly to occur. next task is to determine the variations from that and to find correlations between these variation ætiological factors or alternative treatments ssible he uses statistics to express these variations He es statistical estimates of variations also in designing e extent of his study If the disease under study is e which varies little in its course he limits his number examples. If the course of the disease has many riations—or a wide "lunatic fringe," as the clinical ientist may call it in his despondent mood—he takes is into consideration in making his estimate of the umber of patients to be taken into his study and then oceeds towards that goal If he takes less than he needs s study is deceptively incomplete If he takes more an he needs he wastes his time In this way he plans s study of disease, and with one research finished he asses on to study another disease In this way he comes know disease as a predictable sequence of events, and he knowledge gained becomes the basis the only basis y which the underlying processes of disease in the living atient can be rationally interpreted.

I may be setting my aim too high in describing this ethod of study or this method of study may have less ientific value than I think it has; but assuming that t is a necessary and valuable instrument for one kind of linical research I believe it to be greatly neglected part from a few elementary observations on pulse and emperature, how little we know about the detailed ourse of disease. How rarely does a clinical investigator t through an illness recording the observations and nstrumental measurements for himself How seldom oes the young physician sit through a night recording he pattern of behaviour, of delirium or of sleep in a atient with encephalitis. How infrequently does the oung surgeon train himself in diagnosis by sitting at the edside of a man with ruptured duodenal ulcer to measure he fluctuation of his signs and symptoms during the eriod while the operation is prepared If the illness be rolonged how rarely do we design our observations with regularity of twelve hourly or even daily intervals Most of us come to the patient to observe only the phenomena which custom has predetermined for us, or we take the observations second hand from others who have recorded them for us I am conscious of this in confessing that I myself know very few diseases in this discriminating manner which satisfies my scientific conscience For example, I could not to my own satisfaction, describe measles, or leukaemia or acute rheumatism, or primary herpetiform stomatitis, with their hour to hour or day to-day sequence of significant phenomena precisely determined, measured and accurately recorded Yet this kind of knowledge is one of the bases on which scientific clinical medicine is built It may not reveal and unfold any new natural laws, but the practice of *rational medicine relies on it* for without the power to predict the natural course of a disease, advice and treatment will remain at the mercy of unsubstantial opinions

My claim is that clinical science should correct the bias which has been imposed upon it by dominance of the experimental study of phenomena, and that a few young clinical scientists should be trained in the exact observation and measurement of disease If it be asked what value can these have since diagnosis and treatment are the end all and be-all of practical medicine, my reply would be that it would bring mature and trained observers to the bedsides of patients and that in those circumstances new significant phenomena are likely to be discovered. Even if no new discoveries be made in this way it will at least result in a contemporary knowledge of disease and illness, for the pattern of these changing as they do in the new environments which man creates for himself are not static and eternal

The inaccuracy and inadequacy of our recorded knowledge about disease and illness will become evident if we consult a few examples in textbooks and journals Nowhere in medical literature can I find a complete coherent account of the sequence of clinical events which follows the burnings of a man, a woman, or a child If convulsions occur after burning is their frequency related to the age of the patient or to the extent of the burn? Is the time-incidence of the convulsion, if it does occur limited to the second day of the illness? There is no recorded answer to these questions. Many studies of isolated phenomena of burns have been successfully pursued, but the close relationship of one phenomenon with another has not been established That this should be the case in a disease so easy to observe and to measure is an index both of our ignorance and of faulty observation

On the other hand when we hear a young clinician say after examining and observing a suspected case of meningococcal septicæmia, 'I have been watching the appearance and measuring the changing outline of these purpuric spots over the last six hours, and from this evidence I know that this illness is not meningococcal septicæmia because this illness is at its fiftieth hour and the purpuric spots of meningococcal septicæmia are not that shape at this hour of the illness —when we hear him describing his observations in that way we know that he is heading in the direction of being a clinical scientist But there are many hindrances to this training and many obstacles to that kind of clinical work, which I must now attempt to discuss

Hindrances

This talk about scientists may build them up too much No sensible young man starts out to be a clinical scientist By accident or opportunity he later finds himself heading in that direction and follows the stream; or he comes under the personal influence of someone he likes and wishes to imitate or he is just that ort of chap who must do research because he has a passion for getting things clear in his own mind or for seeing how things tick over and finding no other outlet or way of doing it he tries his hand at clinical research He equips himself to become a clinical scientist and then he is between the physical scientists, who do not understand what he does and the practitioners of medicine and surgery who try to understand what he does He seeks a job either as a full time professional research worker or by combining research with some routine clinical practice The latter is the more difficult path to follow particularly in that clamouring kind of hospital which is lively with many conferences and other distractions. But he may order his life successfully by arranging clearly demarcated periods or days, in the way that Victor Horsley did, when he collects and systematises his *observations*

Hindrance to clinical research lies less in the claims of other clinical responsibilities than in the prevailing attitude of mind towards it—the climate of opinion, as it is now called This attitude of mind begins to take shape in medical schools, where the undergraduate thinks of medical research only as an affair of animal experiment and laboratories (I must exclude from this generalisation the three, or perhaps four *alpha* schools in this country which present a more wholesome picture of research) In the teaching hospitals he is immediately engaged in the excitements of diagnostic medicine, and his teachers are those whose skill is mainly in that branch of medicine. He runs into the danger of confusing clinical science with something called clinical investigation ' and of regarding scientific method as synonymous with the use of diagnostic machinery These misleading impressions are intensified by his preparation for final examinations with their diagnostic exercises as ' long cases ' and short cases.

These impressions about the attitude towards clinical research are strengthened by my experience on a regional hospital board committee which reviews applications for research grants from members of the medical staffs of the hospitals The applications come almost entirely from members of the clinical staffs, and they fall roughly into four categories The majority of applications are for the employment of morbid anatomists, or biochemists, or technicians to do some laboratory research which the clinicians wish to have carried out but in the techniques of which they themselves have had no training The second category consists of requests for secretarial help in *retrospective studies of hospital records* The third category is the request for diagnostic machinery The smallest category is the request for the assistance of a clinical research worker to enlarge and complete a piece of clinical research which is already under way, and which the applicant is conducting for himself

With monies now available from the universities, from endowment funds of hospitals, from the Government research councils, and from the educational trusts, the opportunities for clinical research are now beyond the dreams of what might have been considered possible thirty years ago We can therefore look forward with great interest to the directions in which these forces will flow Human nature being what it is, and human institutions what they are, we must expect that the opportunities will attract those who regard the publication of a research paper as a kind of higher diploma which will increase the chance of their being promoted to a higher clinical post Others will use the opportunities to get from these resources the extra help they need for their routine clinical work in hospitals These frailties can be easily humoured and helped in other ways than by calling them research , but if they must be called research then we must find another name for the kind of work a man does when he devotes himself to the planned and patient observation of disease, which is guided by a substantial working hypothesis

Behind all these opportunities and arrangements I see the urgent need for a due proportion of young doctors who will become physicians and surgeons and family practitioners to be trained in this kind of work otherwise we shall face the position of which E D Adrian warned us last year

> "The pathologists and biochemists will find," he said, "that their time is taken up with measurements of uncertain value in which they are not specially interested and the final result may well be that the work is turned over to specially trained technical experts who are the last people to give a dispassionate judgment on the value of what they are doing"

He went on to indicate the cure for this in saying "The point, surely, is that if such data are to be valuable there must be the right people to consider them"

We are now concerned with the selection, the training, and the working conditions of these right people This brings me back to where I started We are not likely to lack a sufficient number of the right people trained in the study of isolated clinical phenomena and their mechanisms The influence of the schools of physiology and experimental pathology will continue to work in that direction But I greatly fear that the very complexity of these phenomena is withdrawing interest from the planned study of their causative diseases To that extent there is a growth of ignorance about these diseases The tempo of events in some diseases may be so slow that they will be accurately observed only by a general practitioner, or by a family doctor over a period of many years, or the disease may be so uncommon, and its distribution so wide, that special arrangements may be required to gather a sufficient number of examples within the reach of the observers Hospitals as we know them will not be the best places from which this work can be organised If clinical research is to be used to get a full picture of disease, it must equip itself to carry the observations beyond the hospitals and extend the searches which can best be done in family practice and by field survey of random samples of population The methodology of planned clinical observation in family practice and in random samples of the population will become a responsibility of medical schools

I foresee the day when medical faculties of universities will have three provinces of clinical training and clinical research One will be in hospitals, where training and the research will be dependent on the facilities which remain after the demand for specialist forms of treatment have been satisfied. The second province will be a sample of population in their own homes which can be provided in family practice The third will be in expeditions to communities, whether they be in a mining village, a Hebridean island, a Chesterfield Islet, or wherever the inquiry takes them If we are not too pompous about it all, if we can escape the dead hand of dull conformity, if we can get the freedom to make experiments in arranging our institutions, if we can recover the initiative to make the experiments—then our medical schools and teaching hospitals may take on this work. If they fail it is difficult to see how else it can be done.

RENAL FACTORS IN THE PRODUCTION OF HYPERTENSION *

CLIFFORD WILSON
M.A., D.M Oxfd, F.R C P
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON , DIRECTOR OF THE MEDICAL UNIT, THE LONDON HOSPITAL

Nature of the Extrarenal Factor

IT is tempting to speculate that the kidneys and adrenals form part of a homœostatic mechanism which, through the control of tissue electrolytes, maintains arteriolar tone and adapts the blood pressure to changes in the internal environment This must remain an imaginative concept until the specific rôles of the kidney and adrenal in relation to normal and high blood pressure have been determined How far does the availab evidence shed any further light on this problem? In the first place, it must be emphasised that experimental studies have proved only that the various forms of hyper tension associated with renal ischæmia or total nep tomy cannot be sustained (I use this word deliberatel since there may still be some doubt about the in development of hypertension) in the absence of adr cortical tissue , and further that salt and deoxy acetate can, within the time limits of the experiments provide a fairly effective substitute for the adrenal corte in this respect

It may be argued on the one hand that the adren cortex or its substitutes merely provide the physiolo conditions necessary for the maintenance of tone, whether normal or abnormal, and that conditions form an essential background for any hy tensive process, renal or extrarenal In this case hypertension could arise from some pressor mech independent of the adrenal cortex, acting directly on th peripheral arterioles This is the one alternative the other hand, renal and renoprival hypertension ma both result from a direct dislocation of some form adrenal electrolyte control of arteriolar tone

If we could decide between these alternatives we sh have taken an important step forward in und the factors responsible for renal hypertension Th are many observations which favour the second hy thesis of a direct connection between the kidney and adrenal-electrolyte mechanism

Although variations of salt intake have little effect the normal blood-pressure until gross disturbance of b tor has been produced there is considerable evidence hich I summarised in my first lecture that experimental nal hypertension in animals is aggravated by addition salt to the diet and can be reduced by withdrawing salt nversely, hypertension can be more readily produced both salt and deoxycortone acetate if the kidneys are maged or if one kidney is removed These experiments ggest that there is a mutual potentiation between the pertensive effects of renal damage on the one hand d salt and deoxycortone acetate on the other Never less somewhat similar relationships hold for other essor agents and the facts would not be inconsistent ith the theory that there are two unrelated mechanisms ting independently on the peripheral arterioles.

---

* The second Oliver Sharpey lecture for 1953, delivered the Royal College of Physicians of London on March The first lecture appeared in last week's issue

In the second place there is reliable evidence that anges in tissue-electrolyte distribution occur in experi ental renal hypertension Eichelberger (1943) observed increase in extracellular fluid of muscle tissue in dogs ith renal hypertension. Laramore and Grollman 950) found a rise in the percentage sodium content and fall in potassium in the heart-muscle of hypertensive ts. Ledingham (unpublished work) has recently monstrated a significantly raised extracellular fluid lume in heart-muscle in rats with experimental renal pertension this is part of a generalised body increase o. the rise in sodium and fall in potassium are plained by a gain in extracellular fluid It is found at this gradually returns to normal over a period of ree months despite persistence of the hypertension dministration of deoxycortone acetate to normal rats so produces an increase in extracellular fluid Whilst is evidence supports the view that the adrenal regu tion of tissue electrolytes is disturbed in the early ages of experimental renal hypertension it seems robable that this is the result rather than the cause the hypertension.

We need in fact some direct evidence of an excess of drenal pressor factor in the body when the blood ressure changes from normal to hypertensive levels.

The only evidence of this nature of which I am aware derived from the experiment I mentioned in my first cture which demonstrated the effect of adrenalectomy n renoprival hypertension in the parabiotic rat. Return g to this experiment, it will be recalled that bilateral drenalectomy alone in one member of a parabiotic pair roduces no fall in blood pressure but that the same peration reduces to the normal level the hypertension roduced by bilateral nephrectomy Fig 7 represents hese observations diagrammatically

1 Bilateral nephrectomy in rat B produces hypertension ut the blood pressure of A remains normal. An extrarenal essor factor is therefore operating in B which for some eason is unable to affect its partner The most likely xplanation is that the rate of transmission of this factor cross the union is slower than the rate of its inactivation or limination by the kidneys of A.

2. Bilateral adrenalectomy in the nephrectomised rat B educes the renoprival hypertension to normal—i.e., the extra enal factor depends on the presence of adrenal-gland tissue. It is notable that the blood pressure does not fall elow normal as occurs after the same procedure in the ingle rat.)

3 Bilateral adrenalectomy alone in rat B produces no fall n blood pressure as it does in the single rat

From this experiment we infer that after total adrenal ctomy a parabiotic rat by virtue of its vascular union ith a normal partner is able to maintain normal blood ressure but cannot maintain renoprival hypertension Ience it follows that in the hypertensive rat the adrenals nust, in terms of pressor activity be functioning at a igher level than normal or alternatively the adrenal ressor factor is being produced at the normal rate but is ccumulating in the nephrectomised rat owing to the bsence of some renal inactivating mechanism Grollman nd his colleagues (1940) reported that although bilateral

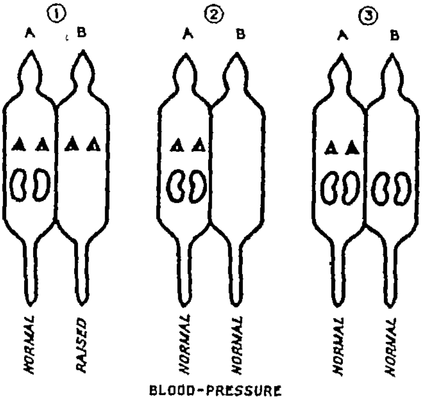

Fig 7—Effect of (1) nephrectomy (2) nephrectomy and adrenalectomy and (3) adrenalectomy alone on the blood-pressure of one member of a parabiotic pair of rats

nephrectomy produced hypertension in dogs whose survival time was prolonged by use of the artificial kidney, no rise in blood pressure occurred if under the same circumstances one kidney was excised and the ureter of the opposite kidney was transplanted into the duodenum or the vena cava—i.e., the presence of non excreting renal tissue apparently inactivated the extrarenal mechanism Assuming that the failure of blood pressure to rise in this second experiment was not due to postoperative shock or some related cause these findings support the theory that normal kidney tissue inactivates the adrenal factor and that after total nephrectomy hypertension is due to the cumulative effect of this factor

If this hypothesis is correct it is essential to find an explanation for the observation that hypertension can be produced by unilateral renal damage without disturbing the opposite kidney It would be necessary to postulate that the production of renal ischæmia in one kidney induced a functional change in the opposite kidney which prevented it from inactivating the adrenal factor In my first lecture I recounted experiments which showed that when hypertension has been present for some time the opposite kidney undergoes a change which enables it to sustain hypertension after removal of the ischæmic kidney This effect is not observed in all hypertensive rats and could not in any case operate until hypertension was established. There is some evidence however that the production of acute ischæmia in one kidney may produce an immediate vascular disturbance in the opposite kidney Gordon and Flasher (1951) have recently observed that after one renal artery of the rabbit had been clamped for five to fifteen minutes, release of the clamp was followed by blanching of the opposite kidney and this phenomenon was shown to be due to a non pressor humoral factor There is therefore some reason to believe that both kidneys are implicated when hypertension is induced by constricting one renal artery More evidence on these lines is essential if renal and renoprival hypertension are to be explained on the unitary hypothesis outlined above

I have so far discussed the rôle of the adrenals on the assumption that some active principle resembling the salt hormone is involved. It is possible that other adrenal steroids may also play a part. Cortisone is known to produce hypertension under certain conditions. Ledingham has reported experiments which show that cortisone can effectively take the place of the adrenals in the maintenance of renal ischæmia hypertension. He has also demonstrated that in adrenalectomised rats the pressor effects of deoxycortone acetate and cortisone have different time relations but are summated when both substances are administered.

We have therefore a variety of evidence which is consistent with the hypothesis of a direct relationship between the kidney and the adrenal electrolyte mechanism in experimental renal hypertension. Lacking more direct proof, such as might be derived, for example, from estimation of cortical steroids in the blood, this hypothesis remains a tentative one; but I believe it provides a new stimulus and opportunity for further investigation. Much of the information has been obtained from experiments on rats subjected to conditions far removed from the physiological state. Nevertheless similar experiments in other animals by many investigators have shown that, although there are definite species differences in response, the same factors seem to be involved in the production of experimental hypertension. There is still some uncertainty whether this mechanism operates in the same manner during the initial development of high blood pressure as it appears to act in chronic hypertension; that again is a subject for future investigation. If from these experiments a reasonable presumption is established that renal hypertension is maintained through some action of the kidney on an adrenal cortical hormone, and that this in turn acts through the influence of tissue electrolyte distribution on arteriolar tone, we have taken the first step towards an understanding of the physiological mechanisms involved in renal hypertension.

Kidney Lesions and Hypertension

I have already referred to the fact that of all the types of renal manipulation which have been used to produce experimental hypertension, constriction of the renal artery is the most effective. High blood-pressure results from a wide variety of structural lesions of the kidney, and it has been with reason assumed that the common operative factor is circulatory impairment analogous to that produced by clamping a renal artery. Since the normal renal blood flow is very large—equivalent to one third of the heart's output—and since the specialised arterial system of the kidney is seriously affected in most forms of renal damage, it is no difficult matter to find an adequate morphological basis for renal hypertension in kidney disease. It was, however, of particular interest when it was discovered that in the rat the development of hypertension could itself lead to severe secondary arterial lesions in the kidney, and that these changes were associated with structural damage to the renal parenchyma which closely resembled in gross and in detail the histological picture of malignant nephrosclerosis in man. Following our original observations several groups of other workers have confirmed these findings in both the rat and the rabbit (Friedman et al. 1941, Schroeder and Neumann 1942, Patton et al. 1943, Flasher et al. 1951). In some of this work the interpretation of the histological changes has been complicated by the occurrence of spontaneous renal lesions and by a failure to distinguish between vascular damage produced by clamping the kidney and acute hypertensive lesions. Goldblatt (1948) held the view that the lesions we reported were due to spontaneously occurring pyelonephritis. Apart from the fact that this condition does not occur in our rat colony the controlled nature of the experiment completely rules out this possibility. Working on an entirely new series of animals Floyer (1951) has confirmed in every detail our original observations. A further argument maintained by Goldblatt is that the lesions are not attributable to hypertension alone but renal failure in some form is necessary for their development. Byrom and Dodson (1948) have answered this criticism by demonstrating the production of rena arteriolar necrosis—which is the essential lesion—whe the blood-pressure was suddenly raised by direct intra arterial injection of saline. It is of interest also tha arterial necroses commonly occur in the viscera of th parabiotic rat in which severe hypertension has bee produced by total nephrectomy, but not in its partner i which the blood pressure has remained normal (Ledingham 1951). A certain amount of confusion has aris from reports that similar lesions are found in dogs in th absence of hypertension following injection of rena extracts and in experimentally produced uræmia followin bilateral ligature of the renal arteries. Vascular necrose after injections of renal extracts are most probably th result of an allergic reaction. In experimental uræmia the severe tissue necroses in the heart and other viscera are of a different character from those produced b hypertension.

That hypertension can give rise to acute arterial necroses in the kidney and other organs is therefore wel substantiated. Why in the same experiment some animals develop these vascular lesions, whilst other with a similar degree and duration of hypertension do not, is still a mystery. I am of the opinion that a sudden rise in blood-pressure to a high level will produce the lesions in most rats; but in animals, as in humans, we must recognise an individual variation in susceptibility.

I described in my first lecture recent experiments which provided additional evidence for our original thesis that the opposite ("untouched") kidney is responsible for the hypertension which persists after removal of the ischæmic kidney. Many months after this operation we observed acute vascular lesions in the remaining kidney and inferred therefore that hypertension perpetuates itself through the production of some change in the kidney, associated with these vascular lesions. This concept of the vicious circle was a natural corollary of the dual proposition that, on the one hand, renal vascular occlusion gives rise to hypertension, and that, on the other, hypertension leads to occlusive vascular lesions.

Application of Experimental Results

The principal difficulty in judging the possible clinic implications of all this experimental work arises from th impracticability of repeating these various unphysiological investigations in man. The main recent developments in the experimental approach to human renal physiology concern clearance techniques; these have given us new and more accurate information about functional disturbances in kidney disease, but no fresh light has been thrown by them on the ætiology of either renal or essential hypertension. Deviations from normal clearance appear more likely to be the consequence than the cause of high blood pressure, and in any event the results of such tests are not appreciably altered when experimental hypertension is produced in animals by renal artery constriction.

Of the three aspects of experimental investigation which I have considered, the first, concerning the search for a renal pressor agent, does not appear in the present state of our knowledge to carry any clinical implications. In the second field, which has involved us in the problems of hormone activity, we are still probing uncertainly among the fundamental issues; here is undoubtedly a sphere of application, but so far filled only with likely intangibles. I shall hope to say a little of these later. The most useful contribution to our understanding of the problems of hypertension in man has been derived from the third experimental topic—the anatomical studies which I have just described. This subject was discussed in detail by Sir Arthur Ellis in his Croonian lectures of 1942. The conclusions he presented then have withsto the test of experience, and I shall refer to some of the briefly, in order to comment on more recent work and on points of interpretation which merit further emphasis

RENAL HYPERTENSION

I will deal first with certain problems of high blood pressure in primary disease of the kidneys, in particular chronic nephritis and unilateral renal disease.

Type I Nephritis

There are obvious morphological changes in type I nephritis which would offer an ideal setting for renal ischæmia hypertension In acute nephritis the diffuse inflammation of the glomeruli, the characteristic epithelial crescent formation of its rapidly progressive course and the generalised reduction in the parenchyma in the more chronic cases might well reproduce an impairment of the circulation analogous to renal-artery constriction There is, however one course of chronic nephritis, which Volhard designated the 'vascular type' in which an additional factor appears to operate When the disease runs this course the patient continues for many years, sometimes for decades with slight to moderate hypertension and with no impairment of renal function; eventually the blood pressure rises steeply often over the course of a few months and becomes fixed at a high level with the subsequent development in many instances of the malignant termination characterised by papillœdema encephalopathy, cardiac asthma and renal failure There is no clinical evidence of recurrence or reactivation of the nephritis to account for this change in the course of the disease, and the histological picture at various stages of the hypertensive transformation shows no vestige of a renewed activity of the glomerulonephritis in its place we see wedge shaped areas of renal atrophy with glomerular interstitial and vascular lesions closely resembling those produced by hypertension in the experimental animal. Corresponding to the later and more rapid clinical progression vascular damage becomes more pronounced, and acute necrotising changes in arterioles and glomeruli are superimposed on chronic organised lesions There is a very strong presumption that secondary hypertensive lesions in the kidneys are responsible for this transformation and that the vicious circle operating slowly at first and then with increasing tempo plays a decisive rôle in the natural history of this common form of Bright's disease.

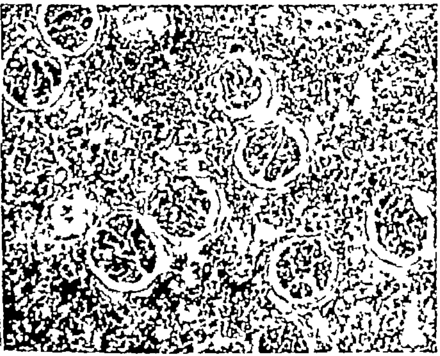

Fig. 8—Chronic ischæmic changes in area of kidney supplied by thrombosed renal artery (hæmatoxylin and eosin. × 83)

Type-II Nephritis

In chronic type II nephritis the clinical and [illegible] features suggest a different sequence. There are many patients chiefly women and children, in whom the disease runs a long course with no considerable degree of high blood pressure But the commonly observed duration of the disease in men particularly, is from three to six years and in its later phases at least, hypertension is prominent A malignant termination is observed in more than half the cases. Hypertensive vascular lesions, acute or chronic are inconspicuous in the kidneys, but the anatomical changes in the glomeruli (and they are the most constant and easily recognisable in the whole of Bright's disease) indicate an insidious disorganisation of the capillaries. The progressive, relatively rapid course of this disorder and its prominent hypertensive features could well be attributed to the circulatory restriction produced by its characteristic glomerular lesion

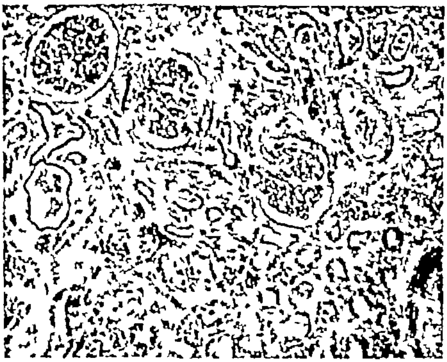

Fig. 9—Endarteritis and glomerular necrosis in section from lower pole of same kidney (hæmatoxylin and eosin. × 83)

Unilateral Renal Disease

The discovery that in the rat sustained hypertension could be readily induced by constriction of one renal artery had an obvious relevance to the recognised association of high blood pressure with unilateral renal disease in man The further observation that removal of the ischæmic kidney more often than not failed to abolish the hypertension has also a parallel in the human disease. It is now generally appreciated that only in

exceptional cases will unilateral nephrectomy reduce the blood-pressure completely and permanently to normal

Whether this persistence of hypertension in man after unilateral nephrectomy can in some cases be attributed to secondary hypertensive changes in the opposite kidney cannot be proved, but there is no doubt that such lesions commonly occur The combination of one contracted kidney with a large opposite kidney, which shows on microscopic examination the picture of malignant nephrosclerosis, is now familiar to most morbid anatomists I have recently encountered such a case of unusual interest

The patient presented with the clinical features of malignant hypertension, and there was a past history of an attack of hæmaturia

Post mortem examination revealed a remarkable picture A main renal artery on the right side was occluded by an *organised thrombus, and the major portion of the kidney was* flabby and congested The lower pole, however, showed on section an entirely different appearance, which was similar to that of the opposite kidney Histologically the upper part of the right kidney showed slight ischæmic scarring such as may be seen in the clamped kidney of the hypertensive rat (fig 8) The lower pole of this kidney and the whole of the opposite kidney, on the other hand, showed gross changes of malignant hypertension with endarteritis, arteriolar necroses, and acute and chronic hypertensive lesions in the glomeruli (figs 9 and 10)

This case provides plain and convincing anatomical evidence that the hypertensive changes followed the production of a renal ischæmic lesion in one kidney The remarkable similarity between the sequence of events, both anatomical and functional, in such instances and in the rat with induced hypertension provides an acceptable assurance of the validity of our experimental method. A number of papers have recently appeared claiming that the incidence of hypertension in patients with unilateral renal disease is no greater than in the general population This may well be, but it does not alter the fact that severe hypertension, sometimes with malignant features, is occasionally encountered in patients with a single contracted kidney, nor should such statistical generalisations be accepted as an argument against nephrectomy, since this may be a life-saving measure The lesion in such cases is commonly a developmental anomaly complicated by chronic pyelonephritis

ESSENTIAL HYPERTENSION

Malignant Essential Hypertension

The observation by Wilson and Byrom (1939) that, in the rat, the histological changes of malignant nephrosclerosis appeared in the untouched kidney, but were absent from the clamped kidney, provided experimental evidence for accepting the "malignant hypertension" of Volhard as a form of essential hypertension rather than as a variety of chronic nephritis It established the fact that nephrosclerosis was a sequel of the hypertension and not its cause, and demonstrated the ischæmic basis of this typically inflammatory renal lesion It explained the severe and progressive course of malignant hypertension and the confusing similarity, both clinical and histological, of the various forms of hypertensive Bright's disease in their late stages

Although the vascular lesions of nephrosclerosis are not the primary cause of the hypertension they may perpetuate and aggravate it by progressively increasing the renal ischæmia We nowadays see patients with this disease in its earlier stages, during the period of development of the malignant features From observations we have recently made on the clinical course, and from renal biopsy studies in patients submitted to sympathectomy, it is apparent that at its onset malignant hypertension is often an intermittent disorder Phases of increased blood pressure may produce papillœdema or encephalopathy which subside during quiescent periods Histologically, active and healed stages of the vascular lesi are found corresponding to the clinical phases Eventua the condition becomes fixed, papillœdema fails to regre and the disease advances with increasing speed might be argued that the primary cause of the increa peripheral resistance in malignant hypertension is first phasic, then continuous, with a terminal rise activity , but the *natural history is more aptly account* for by the vicious circle based on perpetuation a aggravation of the hypertension by secondary h tensive vascular lesions

The natural progress of the various types of hyp tensive Bright's disease *to a malignant terminati* illustrates the desirability of attempting to break vicious circle in the early stages before serious irreversible changes develop in the heart, brain, kidneys The observed fact that reduction of blo pressure by sympathectomy, hexamethonium drugs, non-specific operations—even though this reduction only partial—can retard the progress of the disease *an added argument for the existence of the vicious circ* for these measures do not act on the fundamental cau of the high blood pressure but only modify the con of the disorder by a non specific effect on the level of t hypertension and thereby on its consequences

It is now generally recognised that the clinical ma festations of malignant hypertension, of which papi œdema is the certain diagnostic sign, may occur as sequel to benign hypertension, to the various forms renal hypertension, and occasionally to other rare for of hypertension of endocrine origin—e g , phæochrom cytoma and Cushing's syndrome The term "maligna hypertension" is used by some writers to indicate t clinical syndrome, and by others in the original connot tion used by Volhard to denote the malignant form essential hypertension in contrast to benign hypertensio This dual usage is unfortunate since it tends to obsc again the issue which experimental work has clarifie *It is at the present time particularly unhappy* since the is still a lingering prejudice that essential hypertensio whether benign or malignant, may be due to orga renal arteriolar disease Confusion will be avoided if patients with the picture of malignant hypertension search diligently for the primary cause—whether it chronic nephritis, unilateral renal disease, adren tumour, or essential hypertension , and if, having *fou* the cause, which is not difficult in the great majori of patients, we use the appropriate diagnostic term *designate a case of* pyelonephritis as malignant hyp tension is no less inappropriate than to attach diagnostic label "nephrotic syndrome" to the dise we now recognise as diabetic glomerulosclerosis I emph sise this point since confusion in terminology has *be* the bane of Bright's disease and is largely responsi for the attitude of defeatism which often prevents o recognising obvious disorders of function and *sometim* deprives the patient of urgent and effective treatment

If, then, malignant hypertension may develop in a patient with high blood-pressure, what is the fundament difference in mechanism from the more common beni form, and does the kidney play any rôle in its *develo* ment ? I am sure it is now clearly understood th although the acute destructive vascular lesions which a diagnostic of malignant hypertension may accentua the disorder they cannot play any part in its origi There is so far no evidence of any anatomical basis f the change from the benign to the malignant typ Nevertheless the attitude that the difference is pure a matter of degree or severity is unsatisfying Very hi levels of blood-pressure may long persist in experimen animals and in man with no sign of the maligna features which similar levels rapidly produce in oth individuals, and yet, as Volhard pointed out, *th* *Umschlag*, or malignant transition, may eventually oc

after a decade or more of the benign course. From a combined study of the clinical and histological manifestations of the syndrome I think there is some intimation of a possible difference in ætiology between the early or fulminating syndrome of malignant hypertension and the delayed or chronic type The best approach to this problem is by comparison of the incidence of the malignant termination in renal and in essential hypertension. Kimmelstiel and Wilson (1936) studied the clinical and histological features in 250 consecutive cases of essential hypertension submitted to post mortem examination 4% of the series were clinically and histologically diagnosed as malignant essential hypertension, and less than 1% were of the transitional type representing a malignant termination to a long standing benign hypertension. In renal hypertension on the other hand the incidence of the malignant syndrome is quite different as the following figures show :

	Total cases	*Malignant hypertension syndrome*
Type-I nephritis rapidly progressive	13	4
Type-I nephritis slowly progressive	65	32
Type II nephritis	41	26
	119	62

In this series of cases of chronic nephritis studied in the renal clinic at the London Hospital there were 78 cases of progressive type I nephritis (confirmed histologically) and 41 of progressive type II nephritis 36 in the first group and 26 in the second developed the malignant hypertensive termination—i.e. an incidence of over 50% in the whole series This is of the same order as the incidence of malignant nephrosclerosis in rats with experimental renal hypertension It is apparent that in organic renal disease the malignant termination is a fairly general hazard and is presumably related to the steadily increasing severity of the hypertension associated with progressive renal damage a similar explanation may possibly apply to the small transitional group in which a malignant termination is superimposed on a long-standing benign course for the kidneys in these patients show severe ischæmic scarring But such a background of organic renal disease plays no part in the usual development of the malignant type of essential hypertension. Whilst some of these patients are known to have had benign hypertension for a considerable period in others it is certain that the high blood pressure is of recent origin moreover histologically, chronic ischæmic changes in the kidney may be inconspicuous or even absent I do not think we can escape the con clusion that there is some special disorder of function in those patients with essential hypertension who develop the malignant termination early in the disease This may be in the nature of an abnormally intense response of the arterioles to the pressor mechanism or an excessive activity of the pressor mechanism itself, there is at present no evidence that the kidney plays a primary rôle in this fundamental disorder

Hypertensive Encephalopathy

I cannot leave this subject without brief comment on hypertensive encephalopathy This symptom complex of disorientation, convulsions, amaurosis, and coma occurs in acute nephritis, in eclampsia, and in any form of chronic Bright's disease complicated by the syndrome of malignant hypertension From a study of encephalopathy in acute nephritis, Volhard recognised that renal failure played no part in its development, and for this reason applied to it the term pseudo-uræmia The experimental verification of this conclusion was apparent when in rats with hypertension due to unilateral renal artery constriction we observed the typical syndrome of hypertensive encephalopathy and noted its prompt relief when the hypertension was abolished by excision of the ischæmic kidney Encephalopathy in man, in either acute or chronic hypertensive states, can be similarly relieved by measures which lower the blood-pressure There has been some difference of opinion whether this complication is a result of excessive cerebral vasoconstriction or of cerebral œdema Hypertensive encephalopathy occurred in 11 of our series of acute nephritis (a 6% incidence) In 6 of these patients the cerebrospinal fluid pressure was measured, and in 4 it was normal Furthermore a rise in blood pressure is occasionally observed just before an attack—an observation which favours vascular spasm Dr F B Byrom has recently carried out some fundamental, and I believe decisive, investigations on the underlying mechanism By the introduction of transparent windows into the skull of the rat he has obtained many photographs of the superficial cerebral arteries before and during attacks of encephalopathy He has kindly sent me an account of this as yet unpublished work, and serial photographs (figs 11–13) which demonstrate convincingly the occurrence of cerebral arterial spasm This phenomenon was observed in 57 out of 65 rats with hypertensive encephalopathy In rats with severe hypertension but no cerebral symptoms (148 observations on 88 animals) no spasm was recorded Very occasionally localised ballooning of larger arteries occurred during the attack These experiments are not yet completed, since it is essential to exclude the possibility that some of the changes observed may be artefacts related to the presence of a cranial window in an animal with an expanding brain and irritable hypertensive arteries Nevertheless Byrom draws two firm conclusions first, that the view that the cerebral arteries are too thin-walled to be capable of spasm is no longer tenable, at least as far as the hypertensive rat is concerned, and, secondly, that the irritability of the cerebral arteries is remarkably increased in encephalopathy Organic lesions in the brain were not a necessary accompaniment of encephalopathy and were absent in half the cases, nevertheless arteriolar necroses were frequently found, and it may be that these resulted from excessive vascular spasm or from a resulting paralytic dilatation General cerebral œdema was a late development but vital staining with trypan blue showed local areas of increased capillary permeability and œdema in the cerebral cortex (fig 14) Hypertensive encephalopathy in the rat is reversible to a remarkable degree If the hypertension is abolished by removing the clip from the renal artery the symptoms are promptly relieved, the spasm relaxes, and the cerebral œdema is quickly dispersed Whilst I am not suggesting that any specific renal factor is involved in the production of hypertensive encephalopathy, I Byrom's observations provide another striking of the similarity of hypertensive behaviour in the and in man

Benign Hypertension

In this, the common form of essential hyp as Clifford Allbutt discovered by clinical obse over fifty years ago, involvement of the kidney, in far as the patient is concerned, is of no great There is no evidence that structural changes in arteries or arterioles play any part in the genesis of hypertension, nor in the great majority of cases such changes influence the course of the disease may be that functional vasoconstriction, stimulated b some extrarenal factor, provides a renal mechanism the hypertension, but again there is no evidence for hypothesis Returning to our second topic of experi mental investigation, the possibility that the adren cortex plays a rôle in renal hypertension at once the question of a similar participation in hypertension Elevation of the blood-pressure Cushing's syndrome, which closely resembles hypertension and may develop the malignant term tion, is apparently the result of adrenal cortical over activity Low blood pressure is a diagnostic feature o adrenal cortical failure in Addison's disease, and sub stitution therapy by deoxycortone acetate occasionall leads to hypertension in the course of treatment S restriction is undoubtedly effective in lowering blood-pressure in some cases of essential hypertension. These are the intimations, promising yet intangible, which I have previously referred They may yet lead to the discovery of a common metabolic process underly ing most, if not all, forms of hypertension If there is such a final common pathway I believe it may us also to the method of regulation of the no blood-pressure

I am greatly indebted to my colleagues, first Dr F B Byrom and later Dr J M Ledingham and Dr M A Floyer, who have made a large contribution, both practical and critical to these studies Fig 5 is taken from an article by Dr Ledingham in *Clinical Science* (1951, 10, 423), and fig 6 an article by myself in the *British Medical Bulletin* (1952, 8 316) and I am grateful to the editors of these journals f permission to reproduce the figures

BRONCHITIS especially chronic bronchitis has been an xceedingly popular diagnosis in the British Isles ever ince the term was introduced to medical literature by Badham (1808) During the past century improved methods of investigation have enabled clinicians to place many patients having cough sputum and breathlessness as their predominant symptoms into other diagnostic ategories but there remain many for whom no more ppropriate diagnosis than chronic bronchitis is forthcoming

With a view to establishing some basic facts concerning his rather heterogeneous group a questionnaire has been completed upon 1000 adult bronchitic patients during the period January 1951 to January 1953 The great majority were seen in a special bronchitis clinic held weekly at the Brompton Hospital for this purpose The others were seen at St Bartholomew's, and a few n private practice There was no selection except that he Brompton patients included 362 civil servants who nd had repeated spells of sickness recorded as 'bronchitis' and were referred by the Treasury medical department for an opinion The questionnaire was completed at the Brompton by one of us or the Treasury medical officer and at St Bartholomew's by one of us or his chief assistant. All were checked by at least one of us. The forms were designed so that they could be completed t a single visit to an outpatient clinic about half an hour eing taken for each patient.

Only patients aged 20 or more at the time of interview were included All had chronic bronchitis in the sense in which the term is usually applied—i.e, they had a disease which appeared to be predominantly affecting their bronchi and having cough, sputum and breathlessness as its outstanding symptoms without evidence of any other important primary or precipitating disease of the respiratory or cardiovascular system or other part of the body They all had some degree of disability from either breathlessness or infection or both and the symptoms had persisted, not necessarily continuously for at least a year Each of the 1000 patients underwent physical and radiological examination Some difficulty was experienced in determining the common usage of the term chronic bronchitis' as opposed to asthma Asthma was taken to mean periodic attacks of breathlessness with a feeling of tightness in the chest and difficult expiration No such patients were included unless they gave a clear history of bronchitis before the onset of such attacks

The age-distribution of the 1000 patients shown in table I may be taken as fairly representing that at which this type of patient seeks advice from hospitals in London

TABLE I—DISTRIBUTION BY AGE AND SEX OF 1000 PATIENTS WITH CHRONIC BRONCHITIS

Age (yr)	Males	Females
20–29	23	22
30–39	60	34
40–49	135	53
50–59	353	47
60–69	[illegible]	21
70 or more	[illegible]	3
Total	820	180

The highest incidence is in the sixth decade, a time at which breathlessness often tends to become troublesome

No firm conclusions can be drawn about the distribution by sex Males predominate in a ratio of 4 6 to 1 but even if the civil servants of whom 331 out of 362 were males, are excluded, the ratio of men to women is still 3 3 to 1 The significance of these figures is doubtful since many women were excluded because they had asthma rather than bronchitis also men probably seek advice from hospital earlier than women especially if they are losing time from work. Housewives can often adjust their lives, in respect of work and exposure to adverse climatic conditions, sufficiently to enable them to do their work without undue breathlessness or distress whereas men cannot avoid unfavourable weather and adverse factors at work

In addition to the 1000 bronchitic patients, relevant parts of the questionnaire were completed upon 300 controls of similar age sex and social status The controls were derived from a medical outpatient clinic and from the general surgical wards at St Bartholomew's care being taken to exclude patients who had any pulmonary disease the forms were completed by one of us and his chief assistant.

The analysis fell into two parts

(1) A comparison between 300 patients with chronic bronchitis and 300 comparable controls in relation to family history, respiratory disorders of childhood, allergic diseases, colds in the head smoking habits, and blood pressure

(2) A review of 1000 patients with chronic bronchitis for age and mode of onset age of onset of breathlessness, degree of breathlessness character of sputum clinical severity radiological findings, effect of climate occupation, and living conditions.

Patients Compared with Controls

Age-distribution

Table II shows the distribution by age and sex of 300 controls The relatively large numbers in the younger age groups, compared with the 1000 patients

TABLE II—DISTRIBUTION BY AGE AND SEX OF 300 CONTROLS

Age (yr)	Males	Females
20–29	23	1
30–39	52	3
40–49	80	12
50–59	71	12
60–69	31	6
70 or more	7	2
Total	264	36

300 of the 1000 patients with chronic bronchitis of similar age and sex are compared with these

is due to the difficulty of finding older men and women free enough from respiratory symptoms to act as controls

History of Bronchitis in Relations

Relations being defined as fathers, mothers, brothers, half-brothers, sisters, half sisters, sons, or daughters, the 300 patients had 2248 relations, of whom 256 (11 4%) had chronic bronchitis, whereas of 2137 relations of controls only 82 (3 8%) had chronic bronchitis This difference is statistically significant and is of the order to be expected from clinical impressions, but possibly bronchitic patients are more likely to remember bronchitis in relations than are other people , therefore some allowance should be made for this The 1000 patients had 7786 relations, of whom 803 (10 3%) had bronchitis , this figure may be regarded as reasonably accurate for the hospital class of patient in London

Among the relations of the 300 patients, 677 had died, and in 90 (13 3%) of these bronchitis was considered to be at least a contributory cause of death , the figures for controls were 644 deaths, to which bronchitis at least contributed in 24 (3 7%) The significance of these figures depends on the validity of history-taking , certainly the great apprehension of many bronchitic patients about the outcome of their disease was impressive Bronchitis leads to complications in the lungs and heart and, though it may often not progress very far, it is associated with death in a high proportion of the near relations of patients who have it

A history of allergic disorders was sought among the relations Of the 2248 relations of patients 57 (2 5%) had asthma, 8 (0 4%) hay-fever, and 11 (0 5%) eczema The corresponding figures for 2137 relations of controls were 31 (1 5%) with asthma, 9 (0 4%) with hay-fever, and 6 (0 3%) with eczema No reliable figures could be obtained for migraine or for urticaria

TABLE III—TIME LOST FROM SCHOOL AS A RESULT OF RESPIRATORY INFECTIONS IN 300 PATIENTS WITH CHRONIC BRONCHITIS AND CONTROLS AT OR BEFORE THE AGE OF 12

Time lost	Bronchitic patients	Controls
Nil	221 (*73 7%*)	281 (*93 7%*)
Occasional week	46 (*15 3%*)	16 (*5 3%*)
Habitual absentees	19 (*6 3%*)	2 (*0 7%*)
Total absence of more than 1 year	14 (*4 7%*)	1 (*0 3%*)
Total	300	300

Childhood Illnesses

Table III shows that chronic or recurring respiratory infections were much commoner in patients than in controls The greater differences are seen in the longer absences from school but even absences of an occasional week were greater in patients than in controls By contrast, 73 7% of the patients lost no appreciable amount of time from school through respiratory infections

Bronchitis and pneumonia were by far the commonest serious respiratory infections in childhood in those who subsequently developed bronchitis, and occurred much more often than in the controls Of the patients 67 (22 3%) gave a history of bronchitis in childhood 43 (14 3%) of pneumonia The corresponding f for controls were 7 (2 3%) and 18 (6 0%)

Relationship of Colds in the Head to Bronchitis

The annual mean number of colds among the p was 2 6 and among the controls 1 6 Table IV shows frequency with which colds "went down to the Very few of the patients did not have colds in the and 90% of them stated that they "went down to chest" Colds "went down to the chest" in 27% the controls but did not produce any real disability

Occupational Factors

The predominant occupation of each patient control at ages 15–25, 25–35, and more than 35 was no Table V shows the occupation by the Minister of Lab code at the ages 15–25 for the 300 patients controls, the distribution being similar in each except for a slight preponderance of clerical workers the controls The proportions in the five grades remained similar for patients and controls in of the three age groups noted Both patients controls aged 15–25 were equally distributed light and heavy work, and between indoor and occupations At ages over 35 almost three as many were doing light as were doing work, and the same proportion were working but there was no significant difference in either between the patients and the controls This might first sight appear anomalous, in view of the disa symptoms of chronic bronchitis, but is explained pa by the fact that half the patients were normally emp in light work, largely clerical, which they were able manage provided they were fit for a measure of ment For the rest, the difficulties of learning a trade after the age of 35 are well known, and there a natural tendency for the unskilled and semi to become skilled, thus lightening the amount of he work which might otherwise have been beyond physical capacity

TABLE IV—FREQUENCY WITH WHICH COLDS "WENT D TO THE CHEST" IN 300 CHRONIC BRONCHITICS AND CONTROLS

—	Bronchitic patients	Control
No colds	11	34
Colds do not go to chest	19	186
Colds do go to chest	270	80
Total	300	300

Blood-pressure

The mean blood pressures of the patients and did not differ significantly The mean systolic bl pressure of the patients was 148 4 mm Hg and of controls 142 8 mm Hg , the corresponding figures diastolic pressure were 88 3 and 84 1 mm Hg

If 160 mm Hg is regarded as the upper limit of no for systolic pressure and 90 mm Hg for diastolic, or other or both of these figures were exceeded by (27%) of the patients and 60 (20%) of the contr The difference between the proportions with hypertensi in the bronchitic and control groups is not significant

Clinical Features of 1000 Patients with Chronic Bronchitis

Age of Onset of Bronchitis

Table VI shows a clear pattern for the age of on of bronchitis First there are the catarrhal children do not throw off their respiratory infections In second decade fewer patients develop symptoms Af the age of 20 there is a rapid increase in the num developing bronchitis , the numbers remain st between about 30 and 60, and then decline

TABLE V—OCCUPATION BY MINISTER OF LABOUR'S CODE FOR 300 BRONCHITICS AND CONTROLS AGED 15–25

Occupational code	Bronchitic patients	Controls

Housewife	3	3
Unemployed	1	2
Total	300	300

Mode of Onset of Bronchitis

The mode of onset of bronchitis was considered to be insidious in 524 and acute in 476. Patients having an insidious onset said that they gradually became 'chesty' over months and sometimes years. There was usually an initial period in which colds in the head were followed by expectoration which lasted a few days and caused no inconvenience. Sooner or later the bronchial infection was accompanied by a constitutional upset, after which the symptoms of infection or breathlessness persisted. Patients having an acute onset considered that the precipitating pulmonary infection was acute bronchitis in 342, pneumonia in 118, whooping-cough in 13, and measles in 3. Associated causes at the time of onset included coryza 140, influenza 72, gassing in the 1914–18 war 27, surgical operations 13, pleurisy 7, sinusitis 6, mental shock 6, and childbirth 3.

There is no sharp division between these two groups, but nearly all the patients felt that their symptoms had either developed gradually over many months or years or else had appeared suddenly after an acute respiratory infection. Indeed many in the acute group thought that a single respiratory infection suddenly converted them from healthy beings into respiratory invalids, and this was particularly so in the elderly.

Characters of Sputum ✓

Table VII shows the obvious increase in the *quantity* of sputum in the winter and during exacerbations of bronchitis. Some patients did not ordinarily expectorate at all; some stated that they swallowed any excess of bronchial secretions; others who would be regarded as having chronic bronchitis in a loose terminology perhaps would have been classified more correctly as having 'pure' emphysema.

TABLE VI—AGE OF ONSET OF BRONCHITIS IN 1000 PATIENTS WITH CHRONIC BRONCHITIS BY DECADES AND SEX

Age (yr.)	Males	Females	Total
0–9	74	37	111
10–19	50	16	66
20–29	128	41	169
30–39	157	33	190
40–49	169	32	201
50–59	194	19	213
60–69	44	2	46
70 or more	4	—	4
Total	820	180	1000

Inquiries into the *colour* of sputum were made in an attempt to differentiate between mucus and pus. The reliability of this method has been tested in another context and has been found to be accurate in more than 90% of cases. The figures demonstrate strikingly that in chronic bronchitis there is usually a mucoid sputum. Grey-white sputum was present in the majority both in summer and in winter; in about half of these it remained mucoid during exacerbations. A minority of patients, about a third, had mainly purulent sputum; 147 had purulent sputum all the year round and during exacerbations.

The *viscosity* of the sputum was described as loose and sticky with equal frequency.

The figures for the *time taken to clear the chest on waking* are included because of their very great importance to the patients concerned. No less than 367 patients indulged in that unpleasant ritual which causes at least a quarter of an hour's distress to themselves and to the other members of their households; in 222 the procedure extended into the summer months.

There was a history of *hæmoptysis* in 172 patients, 135 males and 37 females; it rarely amounted to more than blood-streaked sputum. This notoriously misleading symptom is very difficult to assess, and undoubtedly at times the blood came from sites other than the bronchi. Perhaps the safest plan is to accept the figure at its face value and to remember that, although chronic bronchitis is a recognised cause of hæmoptysis, there will always be some patients in whom the cause of a hæmoptysis is never discovered.

TABLE VII—CHARACTERS OF SPUTUM IN 1000 PATIENTS WITH CHRONIC BRONCHITIS

—		In summer	In winter	During exacerbations

	16–60 min.	222	367	—
	More than 1 hr.	44	125	—

Breathlessness

An attempt was made to differentiate between bronchospasm and constant breathlessness. Bronchospasm was regarded as a state of wheeziness in which the smaller air passages were apparently narrowed and unduly sensitive to changes in temperature, atmospheric impurities, and exacerbations of infection. Constant breathlessness meant abnormal breathlessness on exertion all the year round compared with healthy persons of the same age. Naturally many patients had both types of breathlessness.

Some 123 patients stated that they had no breathlessness; these were largely in the younger age-groups, being 25% of those aged less than 50 and only 6% of those aged 50 or more. Table VIII shows that 70·6% were considered to have bronchospasm and 52·1% constant breathlessness at the interview. No patient aged less than 20 was included in the series, and (see table VI) 346 patients stated that their bronchitis began at some time in the first three decades of life. Table VIII shows that 92 (26·6%) of these had proceeded to bronchospasm during these decades and 66 (19·1%) to constant breathlessness. These figures are far below the mean for the whole series and indicate that breathlessness is largely a symptom of middle or later life. Many of the

TABLE VIII—AGE OF ONSET OF BRONCHOSPASM AND OF CONSTANT BREATHLESSNESS IN 1000 PATIENTS WITH CHRONIC BRONCHITIS

Age-group (yr.)	Onset of bronchospasm	Onset of constant breathlessness
0–9	19	19
10–19	16	10
20–29	57	37
30–39	131	71
40–49	183	140
50–59	230	170
60–69	70	65
70 or more	4	9
None	291	479
Total	1000	1000

younger patients did not complain of breathlessness, their symptoms being largely attributable to infection

The differentiation between bronchospasm and constant breathlessness may seem to be unjustifiable and is defended on clinical grounds alone There is no doubt that the bronchi of most of the patients were abnormally sensitive to infections and changes in atmospheric conditions, and that a feeling of constriction was readily produced in such circumstances From the standpoint of treatment, especially prophylaxis, this symptom had to be carefully assessed By contrast, and often in addition, many patients seemed to have reached a state of constant breathlessness, presumably from a combination of mucosal œdema, chronic inflammation, bronchial secretions, and emphysema, but no attempt was made to assess how much of this could be attributed to emphysema

Clinical Assessment of Severity

A rough clinical assessment of disability was made in each case Some 341 patients were mildly disabled, having no more than occasional absences from work through bronchitis and being able to lead a normal life between attacks In the moderate group, numbering 435, respiratory symptoms were an appreciable handicap to ordinary existence, and often there were spells of sickness for several weeks or a few months The severely disabled, who amounted to 224 patients, could do no more than light work, and some were unfit to work at all

A relatively high proportion of the younger patients had a mild disability The moderately disabled were evenly distributed between the age groups The proportion of severely disabled rose from 13% of those aged less than 50 to 26% of those aged more than 50, reflecting the chronicity and progressive nature of the bronchitis and the diminution of respiratory reserve with advancing years

Ætiology

Reaction to Weather

The seasons of the year in which the patients considered their symptoms were worst were as follows winter 857, autumn 65, summer 37, and spring 24, the remaining 17 patients being unaffected by seasons

All the patients were specifically asked which atmospheric conditions adversely affected their bronchitis, affirmative answers being fog 744, wet 698, cold 435, hot 62, and dry 20 In addition, symptoms were aggravated in 440 on suddenly going from a hot to a cold atmosphere, and in 174 on going from cold to hot

Winter, being the time of unfavourable climatic conditions and also of respiratory infections, naturally sees an increase in exacerbations of bronchitis Fog was singled out as the most constantly aggravating climatic factor, but wet, particularly dampness as opposed to rain, was only slightly less frequently mentioned and probably accounts for the perpetuation of more bronchitis than fog because it is present so much more often in the London area The much lower incidence of aggravation by cold is significant Many patients who were considerably upset by fog and dampness firmly maintained that they were unaffected by dry cold, a feature which may have a considerable bearing on the choice of habitat and occupation

Smoking Habits

The numbers of non smokers were 40 (5%) males and 66 (37%) females The mean daily number of cigarettes among smokers was 18 5 for males and 11 8 for females, 1 oz of tobacco being equivalent to 30 cigarettes Table IX shows that more than half the smokers felt that smoking aggravated their bronchitis, and that a surprisingly large number had abandoned or reduced the habit with benefit

TABLE IX—TOBACCO HABITS OF 1000 BRONCHITICS

—	Yes	No	Don' kno
Does smoking aggravate bronchitis ?	479	381	3[illegible]
Has smoking been abandoned or cut down because of bronchitis ?	532	359	[illegible]
If " yes " has bronchitis improved ?	395	136	[illegible]

There were appreciably fewer non smokers among th 300 patients than among the controls, the figures 27 (9 0%) and 62 (20 7%) respectively The mean number of cigarettes among the smokers was simi in the two groups, being 18 2 for patients and 1 for controls

Home Conditions

Of the 1000 patients only 43 considered that hom conditions contributed to the onset of bronchitis, dampness was blamed by 22, other causes including air damage, overcrowding, and cold Home condition were considered to have adversely affected the course the bronchitis by 66 patients, 40 of whom blame dampness

Adverse Occupational Factors

Of the 1000 patients 177 were prevented from continuing in an occupation because of bronchitis, breathlessness was given as the main reason in 98, and exacerbations of infection in 67 Of the 177 thus prevented 114 found alternative work, most of the remainde were unfit to work or had retired, often prematurely, and only 4 were unable to find suitable work

The principal factors at work which the patient considered as aggravating their bronchitis were chang in temperature and draughts (175), dampness (148), co (132), dusts (129), smoke and fumes (111), and contracting infections from contacts (83)

There is no doubt that climatic factors exert a considerable influence on the symptoms of chronic bronchitis For those employed indoors the temperature and humidity of their place of work may well determine wheth they dare risk the journey from home Overc may lead to an excessive spread of respiratory infections Those who work both indoors and outdoors are particularly exposed to changes of temperature Outdo workers (many bronchitics prefer to work out of doors) are forced to regulate their activity to the prevailing climatic conditions, especially in the winter months.

Of the formidable array of dusts which were incriminated more than half were related to houses, coal, books and papers Others included wood shavings, packing materials, upholstery, paint, and flour Almost any seems to be a potential irritant Possible irritant specifically mentioned in this series—e g, asbesto cement, cork, wool, lead, lime, marble, printers' ink, talc and chromium—caused the patients to seek elsewhere

Fumes and smoke were another potent source bronchial irritation The products of combustion coal were mentioned most frequently Some 51 males aged 51–69, were exposed to gas in the 1914–18 war 27 of these dated the onset of their bronchitis to gassing and most of the remainder thought it aggravated th bronchitis, although sometimes the onset was man years after the gassing Among other irritants wer exhausts from motor cars, sulphuric acid, acetone benzene, caustic soda, and paint spraying

Discussion

Assessment of the clinical pattern of a slowly progressive disease like chronic bronchitis by the analysis of questionnaire can never be more than approximatel accurate However carefully the questions are framed the answers are bound to be influenced by personal bia on the part of both the patients and the interrogators These difficulties were overcome to a great extent in his series by the completion of a comparatively large number of forms and by limiting the interrogators to a few who knew each other well and worked in the same clinics The object of the investigation was to obtain information about the relative importance of some of the commoner clinical features of chronic bronchitis with a view to the study of selected aspects in greater detail at a later date

The high incidence of bronchitis among the relations of bronchitic patients, the figure being three times as great as for controls, suggests a hereditary predisposition This is probably the correct interpretation, since social and economic factors were eliminated as far as possible by making every effort short of visiting their homes o obtain comparable groups of patients and controls Also the part played by cross infection within the families although virtually indeterminable is unlikely to be important because of the late onset of bronchitis in most of the patients

Of the factors which aggravated the symptoms many were related to the quality of the inspired air Fog wet cold, and changes of temperature were frequent ources of irritation The habit of smoking tobacco had been curtailed or abandoned by more than half the patients. Various dusts fumes and smoke caused irritation at times Indeed almost any deviation from a clean warm dry atmosphere seems to be a possible source of aggravation of symptoms The effect of these features on the patients mode of life and capacity for work was often considerable.

Particular attention was paid to the characters of the sputum and the nature of the breathlessness since these comprise the outstanding symptoms of chronic bronchitis A review of the findings sheds some light upon the significance of infection bronchospasm and onstant breathlessness in this disease

Infection was considered to have been present at the onset of respiratory symptoms in every case It varied from a comparatively mild attack of bronchitis to a fulminating pneumonia At the time of interview 85% f all the patients stated that they had colds which went down to the chest, which strongly suggests the sustained influence of infection on the course of the bronchitis In 147 patients there was a purulent sputum in the summer and winter and during exacerbations These are the patients who can be labelled 'chronic bronchitis' with the greatest degree of confidence The part played by infection in the production of mucoid sputum is a matter of controversy Almost always the volume of sputum increased during exacerbations, and in about a third it remained grey white or mucoid Hence at least in some of these infection acted as a stimulus to the further production of mucus Whether or not infection alone can sustain a mucoid sputum through the winter months or all the year round is a uestion in urgent need of further clarification Of the 23 patients having no breathlessness, the majority had predominantly mucoid sputum which usually became purulent during exacerbations. To regard such patients having catarrhal bronchitis' is not entirely justifiable Certainly infection was closely connected with both the onset and the continuance of symptoms, but other factors—e.g., climate atmospheric impurities, and hereditary predisposition—undoubtedly played a part Indeed, here is the crux of the problem of the genesis chronic bronchitis Patients usually middle-aged men having been subjected to an intricate combination of environmental and hereditary factors for many years, find that pulmonary infection leaves them with an intractable mucoid sputum If this be designated a catarrh, an inflammatory basis is implied The alternative is to regard the infection as a sensitising agent which leads to overactivity of the mucus-secreting elements of the lungs Whichever is the correct explanation such patients are singularly prone to superadded bronchial infections.

No less than 70 6% of the patients were considered to have unduly sensitive bronchi and were regarded as being subject to *bronchospasm* In a way this figure is misleading because chronic bronchitis was not diagnosed unless there was a disability which persisted and at the time of interview 87 7% of all the patients had either spasmodic or constant breathlessness or both A large number of these patients, probably the great majority, would not have been regarded as having chronic bronchitis if they had not been breathless The relationship between bronchospasm and excessive mucoid secretions was not studied in this investigation but external stimuli particularly fogs seem to be incapable of producing one without the other

Constant breathlessness was present in 52 1% of the patients. Interpretation of the significance of this figure is not wholly possible. It is intended as a very rough guide to the incidence of emphysema Emphysema was not specifically investigated, and no physiological function tests were done The radiological findings showed good evidence of emphysema in 20% of the patients but this figure is undoubtedly an underestimate Emphysema is an almost invariable complication of chronic bronchitis, provided the bronchitis persists long enough but it is an insidious process and unless there is radiological evidence of bullæ, cannot be diagnosed in the early stages Hence bronchitics cannot be rigidly divided into those with and those without emphysema In a clinical sense, however advancing emphysema leads to increasing constant breathlessness, to which eventually cardiac insufficiency may contribute. If the present series is judged according to this symptom alone, there was suggestive evidence of emphysema in about half

Summary

A questionnaire was completed on 1000 patients with chronic bronchitis A comparison was made between 300 of these and 300 controls matched for age sex and social status

Chronic bronchitis is largely a disease of middle aged men

There is a fairly strong family history

The adverse effects of atmospheric conditions occupational factors, and smoking are discussed.

The types of sputum and breathlessness are considered

Our thanks are due to Dr H J B Galbraith, chief assistant to St. Bartholomew's Hospital and Dr W E Chiesman and Dr V C. Medvei of the Treasury medical department, for their invaluable assistance; and to Dr J R May senior lecturer in bacteriology at the Institute of Diseases of the Chest Dr Lynne Reid research assistant in morbid anatomy at Brompton Hospital and Mrs. Elsie Small, of the British Red Cross Society for their continued encouragement and help during the investigation

ORBITAL LEUCOTOMY

(ISOLATION OF THE ORBITAL CORTEX BY OPEN OPERATION)

P Macdonald Tow
Ph D, M B Lond

Walpole Lewin
M S Lond, F R C S

From the Nuffield Department of Surgery, University of Oxford

Early in the many published reports on the frontal lobe and its functions there have been references to a difference between its superior and inferior surfaces That there might be some such difference in function is not a very surprising possibility, but in the recent work on frontal ablations for mental disorder competent observers have come to the conclusion that the frontal areas are functionally equivalent

From a twelve years' clinical study of 300 cases of cerebral trauma Kleist (1934) concluded that there was a definite and recognisable difference between the syndromes resulting from lesions of the superior and the inferior surfaces of the frontal lobe involvement of the supero-lateral surface led to disturbances of intellect and psychomotor activity, whereas lesions of the orbital surface produced predominantly emotional changes, usually euphoria or simplicity, and less often depression with inactivity Though the precision of his conclusions has been criticised because of the type of material on which it was based, his work was a very thorough and painstaking attempt to differentiate the functions of the lobe on purely clinical grounds

Rylander (1939) also remarked that earlier workers had considered that the basal part of the frontal lobe played an important rôle in emotional life, and he believed this too, for in his own classical material he thought there were distinct changes in emotional tone in 22 out of 24 patients with lesions involving the orbital region

Experimental studies on the orbital cortex are mostly of recent origin, but Spencer (1894) found that faradic stimulation in the rabbit, cat, dog, and monkey led to respiratory arrest This and other autonomic changes have since been described by Bailey and Sweet (1940), Ruch and Shenkin (1943), and Delgado and Livingston (1948) Ablation of the orbital cortex in monkeys has been done in Fulton's laboratory by Livingston et al (1948b) the monkeys became active (but they gained weight in spite of this), easily tameable, and free from excessive fear In man Livingston et al (1948a) reported that stimulation of the orbital cortex transcortically during the exposure afforded by leucotomy also produced autonomic effects

McLardy and Meyer (1949), working on necropsy material have paid considerable attention to the differing effects of surgical lesions in various parts of the frontal lobe From an extensive study of clinical and anatomical relations they could find no great difference between the sites of lesions associated with clinical improvement and of lesions associated with the greatest personality change They suggested, however, that, from their evidence, there might be a rather greater association of clinical improvement with lesions involving isola- of the orbital cortex, but they emphasised that their result was derived from clinical material What is required is an alternat to the standard leucotomy which will produce co parable benefits without the undesirable side effe of the operation, principally personality changes a in some cases persistent incontinence and metabo disorders

Our trial of orbital leucotomy was based on the hyp thesis that the balance of evidence in the past has be that the orbital surface, rather than the superola surface of the lobe, is concerned with the predo emotional and affective aspects of behaviour, coupl with the working assumption that general personali damage is roughly proportional to the amount of front tissue destroyed In this sense we regarded the opera equivalent to a first step in narrowing down the full leuc tomy procedure In our final choice of the orbital we were influenced by the work of Scoville (1948, 194 who had introduced a technique for "undercutting"

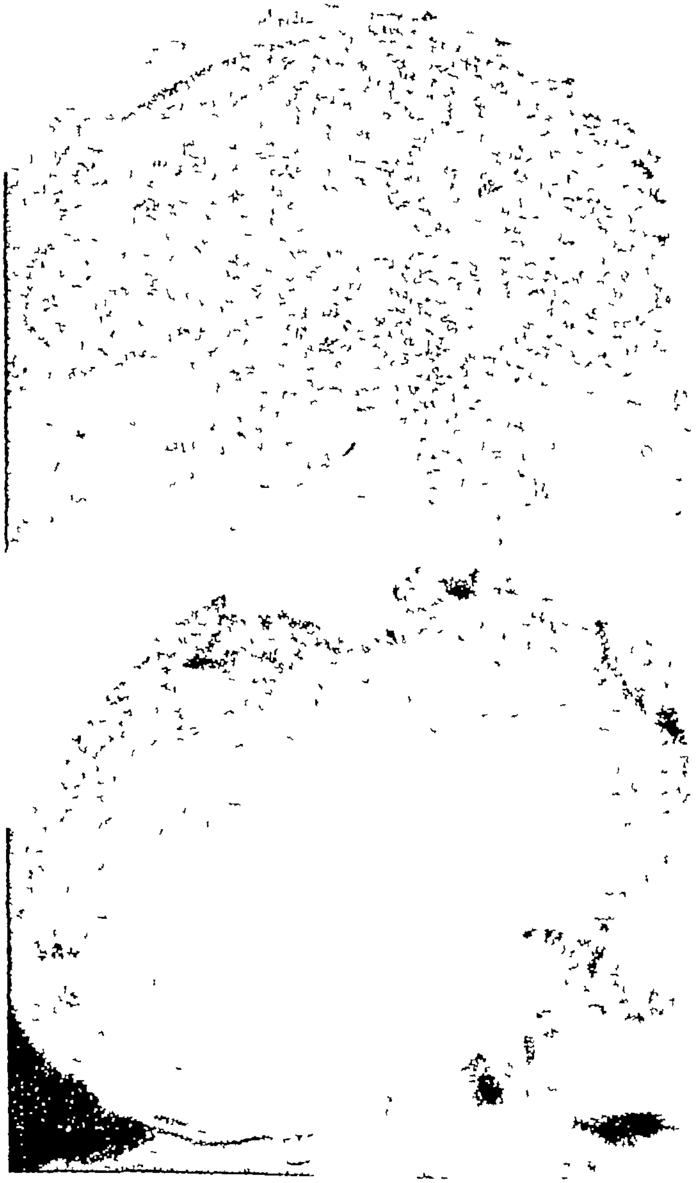

Fig 1—Radiographs of skull showing positions of trephine holes and silver clips site and depth of orbital leucotomy above, anteroposterior, below,

three surfaces of the frontal lobe. We were impressed by some of his early results from operating on the orbital cortex, and in this country some early trials of the operation by one of us with Mr Geoffrey Knight had yielded promising results. The operation follows closely Scoville's technique.

The Operation

The operation consists in making a line of cleavage with a brain spatula and a fine suction tube at the junction of the grey and white matter above the orbital grey matter on each side, extending from the frontal tips back to the level of the base of the anterior clinoid processes, with interruption of the long and short association fibres to the thalamus and to the adjacent frontal cortex. In some cases in this series it was found necessary to sacrifice a main venous tributary running across the face of the frontal pole, but apart from this no major vessels are divided. By operating under direct vision and with reference to the landmarks to be described below, one attempts to produce a discrete isolation of the orbital cortex without damaging, at least macroscopically, the adjacent frontal cortex or its blood supply. To confirm the site and depth of the section we have at the end of the operation placed silver clips mounted on small pieces of fibrin foam at the posteromedial limits of the section and taken postoperative radiographs. This method of localisation is open to the objection that the pieces of fibrin foam may not be placed accurately or may become displaced, particularly when cerebrospinal fluid is running freely. Nevertheless the position of the silver clips as seen in the lateral view (fig 1) gives some indication of the plane of section. Within these limitations the postoperative films in these patients confirmed that in 16 the operation had been limited to the orbital region. In the other 4 the clips were shown to be rather higher in the frontal lobes than usual, suggesting that in these instances more than the orbital cortex may have been isolated. Of these 4 patients 1 recovered, 2 were improved, and 1 was unchanged.

Technique

Preliminary radiographs of the skull are taken to determine the size and extent of the frontal sinuses. All our patients were operated on under general anæsthesia.

With the head slightly extended, a small coronal scalp flap is marked out at the anterior margin of the hair line. After the scalp has been incised, the pericranium and temporalis muscle on each side are cut in the same line and stripped down with the scalp to the level of the orbital ridges to expose the frontal bone subperiosteally. Bilateral trephine holes (3·75 cm. in diameter) are made lateral to the frontal sinuses, just above the orbital ridges and bounded by the lateral borders of the frontal bones (fig 1). On each side a cruciate incision is made in the dura to expose the anterior face of the frontal pole. A transverse incision, 2·5–3·0 cm. in length and situated 1·0 cm. above the orbital roof, is made in the cortex through to the white matter. The frontal pole is now lifted up as in a pituitary approach to the base of the anterior clinoid process. This represents the level of the posterior extremity of the cut to be made, and its distance from the cortical incision is measured. The direction of the orbital roof is also noted. Scoville's spatula forceps are inserted into the cortical incision parallel to the direction of the orbital roof, and, the blades being used as retractors, the white matter is sucked out with a fine sucker tip under direct vision. The medial limit of the posterior extent of the cut, over the clinoid region, is a good centimetre posterior to the lateral limit. Frequently when this point is reached, cerebrospinal fluid comes up from the cisterna chiasmatica. The medial and lateral borders of the section are defined by gentle suction until the grey matter on each side is reached. The depth of the section varies from 5·0 to 5·5 cm. (fig 2). Because the natural tendency is to angle the forceps upwards, direction and depth require repeated checking. *If the section is in the correct plane,* there is very little bleeding, and at the end of the operation it is not difficult to secure hæmostasis. The dura is closed with silk sutures, the bone discs are replaced, and the wound is sutured in layers.

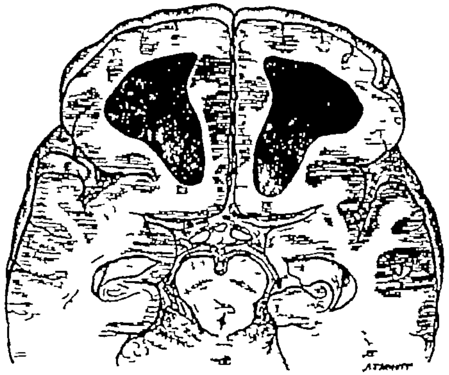

Fig 2—Brain preparation showing site of orbital leucotomy (black area).

Operative Risks

Between January, 1950, and December, 1951, 20 patients underwent orbital leucotomy [*]: they were aged 20–63, 4 of them being aged more than 55.

There were no operative deaths, and the only fatality in this series so far took place seventeen months after operation. This was in case 3, a female paranoid schizophrenic, aged 40, who improved sufficiently after operation to return home. She collapsed and died suddenly while alone in the house. Necropsy done elsewhere showed macroscopic evidence of cerebral atrophy and some pulmonary congestion; in particular no other intracranial complication was seen. Unfortunately, the brain was not made available for further study.

Recovery from the anæsthesia was uneventful: there was very little general disturbance, the wounds healed satisfactorily, and there was no postoperative infection or hæmatoma. In 1 case a clot was suspected three days after operation, but on re-opening none was found, and convalescence was satisfactory. The incidence of postoperative incontinence, epilepsy, and other changes is discussed below.

The Patients

All in this series were psychiatric patients in whom other treatments had failed to produce any substantial improvement in the mental state and, when surgery was considered, the possibility of spontaneous remission was remote. They all required hospital treatment: a typical state of affairs at the time of operation was that the patient had been ill for several years, usually becoming much worse, and that recently or within the preceding two years had become ill enough to need constant inpatient care.

The patients were aged 20–63: 11 being aged 20–40, 8 40–60, and 1 63. There were 9 men and 11 women. In all the clinical picture was florid, and the group was a fair sample of psychiatric inpatients. In half of them rapport was possible, insight was present in varying degree, and there was no extreme deterioration of the personality; in the others rapport was bad or impossible and degeneration of behaviour had begun.

Our patients were selected primarily by the presence of great tension and accompanying disturbances of behaviour: in fact our criteria were not very different from those now used by many physicians for standard leucotomy. However, from all patients referred for operation we selected for orbital leucotomy those who had exceptionally severe tension, anxiety, agitation, or outbursts of impulsiveness uncontrolled by other means In this series we did not include any very chronic or grossly demented schizophrenics The accompanying table lists the diagnoses

---

[*] 1 other patient had a full orbital leucotomy during this period but after another psychosurgical procedure: therefore he has been excluded from this series.

10 of the patients were frank schizophrenics, of these 2 had exceptionally well preserved personalities, and 3 others were very well preserved for the type of illness involved By classical subgrouping, 1 was a schizophrenic simplex, 2 were catatonic, 3 were hebephrenic, and 3 were paranoid In the 10th patient the illness began in the puerperium She developed into a catatonic type of schizophrenic, there was no evidence of any infection All of these were disturbed patients, tense, suicidal, or impulsive 2 other patients exhibited schizophrenic features on occasions, but since they presented throughout their illness primarily as severe anxiety states, with constant tension and feelings of apprehension or dread, they have for brevity been referred to as such in the table

The remaining 8 patients had predominantly affective illnesses with depression 1 case of manic depressive illness presented mostly as mania

Results

The results have been assessed on the general clinical state of the patient compared with his preoperative condition, particularly as regards tension, impulsiveness, and aggression, features of particular interest in this series of patients The patients have been observed throughout their entire postoperative period to date, which now extends from one and a half to three years, all the discharged patients have been followed in their own homes Our experience is that recovery or improvement takes place in the first few weeks or months, and that its pattern does not differ significantly from that seen after standard leucotomy

RECOVERED (7 CASES)

7 patients have wholly and satisfactorily recovered from the illness with which they presented for operation They are all at home, and, although we are aware that this is not a universally valid criterion, in the case of 5 of them, who before operation seemed almost certain to be chronic hospital patients, this fact alone appears to be a good measure of their clinical recovery

In this group there were 5 patients (cases 4, 7, 14, 18, and 19) with essentially affective conditions All were able to be discharged symptom-free a few weeks after operation None has since had any relapse, and they have no complaints, on the contrary, 2 have repeatedly expressed their happiness and well being Case 4, called an aggressive psychopath, had at times had depression and also showed schizoid features, she had been in hospital for one and a half years Six months after operation she was discharged from hospital, and she has remained well since

Two other patients in this group (cases 6 and 12) were schizophrenic Case 6 was an unremitting catatonic type of schizophrenic and needed continuous care in a ward for disturbed refractory patients Her recovery took place gradually in the first three months after operation, and by the fourth month she was given full parole She was discharged, and six months after the operation she had completely recovered and was adequately caring for her house and family Case 12 was the only hebephrenic schizophrenic in the recovered group

The clinical details of 2 of these recovered patients are recorded

Case 7 —A married woman aged 39, first became ill twenty two years before operation When young she was normally sociable with a healthy range of interests She had her first attack of mania at the age of 17, and another four years later She would cease to sleep and would go off her food, soon she would be restless and confused talk rapidly and foolishly, and finally start doing acrobatics She saw men calling her to God Attacks gradually increased in frequency up to the end of her illness when she was rarely well for more than a week at a time She became more and more violent and in her attacks until these were regular features Occasiona the attacks of mania were preceded by a brief period depression and then at times she had been suicidal She been admitted to hospital on three previous Treatment by continuous narcosis had failed, and convulsive therapy, which had been given on several had been quite ineffective except in a most temporary

After operation she immediately became clear and oriented but was amnesic for the operation and for her episodes before it She was transferred to a quiet ward soon settled into a quiet orderly routine By three after operation she had several active interests, and months later she was discharged fully recovered Now, and a half years after operation, she has remained virtua symptom free to date—far longer than any recent remissi and is working happily and efficiently as a housekeeper

Case 12 —A woman, aged 35, first became ill some years before operation For two years her illness had consist only of generalised apathy, with bad headaches, loss appetite, and rather queer and unaccountable behav but she then began to develop bizarre thoughts and unpredictable behaviour, with much emotional disturba She complained to her doctor of awful dreams and of fears going mad She believed that everyone was trying to stop h from dying From then on she behaved in various erratic peculiar ways Often she seemed totally lost in hallu She said she had come from a grave, and asked people to c her throat She would look for a long time over her ri shoulder, and often she was silent for long periods Later she became totally inaccessible and manneristic, with stereoty repetitions She did not improve at all after twenty f electroconvulsive treatments, for a time she was given th treatments weekly because they seemed to help her slightly but it was eventually decided that a limited surgical operati would give her the best chance of a useful recovery

After operation —She was still very schizoid and fatuo in manner a month after operation, but could cc rationally if pressed Two months after operation she much less silly and fatuous and was a little euphoric She worked well in the hospital laundry and continued to

CASES AND RESULTS

Case no	Diagnosis	Duration of illness before operation (yr)	Length of follow up after operation (yr)	Result
1	Chronic anxiety state	14	3	Improved slightly
2	Paranoid schizophrenia	12	3	Improved 2 month relapsed
3	Paranoid schizophrenia	9	$1^{1}/_{2}$	Improved (died later)
4	Aggressive psychopath	11	$2^{3}/_{4}$	Recovered
5	Manic depressive psychosis	4	$2^{3}/_{4}$	Improved
6	Schizophrenia catatonic	2	$2^{3}/_{4}$	Recovered
7	Manic depressive psychosis	22	$2^{3}/_{4}$	Recovered
8	Paranoid schizophrenia	8	$2^{3}/_{4}$	Improved 6 m relapsed
9	Involutional melancholia	11	$2^{1}/_{2}$	Improved
10	Agitated depression	5	$2^{1}/_{2}$	Improved
11	Hebephrenic schizophrenia	2	$2^{1}/_{2}$	Improved 9 month relapsed
12	Hebephrenic schizophrenia	7	$2^{1}/_{4}$	Recovered
13	Catatonic schizophrenia	3	2	Improved
14	Agitated depression	3	2	Recovered
15	Schizophrenia simplex	6	2	Improved
16	Agitated depression	10	$1^{3}/_{4}$	Improved 2 month relapsed
17	Hebephrenic schizophrenia	13	$1^{1}/_{2}$	Improved slightly
18	Chronic anxiety state	4	$1^{1}/_{2}$	Recovered
19	Agitated depression	12	$1^{1}/_{2}$	Recovered
20	Catatonic schizophrenia	6	$1^{1}/_{2}$	Unchanged

7 recovered 8 improved 5 no change

in a placid way Nine months after operation she was discharged recovered and obtained a simple repetitive part-time job Three months after this she was offered a full time job in the same firm, and she has remained well and self supporting to date two years after operation

IMPROVED (8 CASES)

In this category have been placed those patients who after operation have been freed from any of the dominating or persisting symptoms of their presenting illness have gained contact with reality or have achieved a generally more useful adaptation

The improved group includes 4 schizophrenics who had been ill for three six, nine and thirteen years and were subject to severe outbursts of violence and aggression There has been no return of these outbursts since operation The other 4 rated as improved had affective disorders in which there was constant tension and much subjective suffering which disappeared at various lengths of time after operation In 1 case of chronic anxiety state there has recently tended to be some slight return of tension but with this exception these patients have remained quite free from objective signs of tension and subjective feelings of anxiety

4 of these patients have been discharged from hospital of these 2 are now working two and a half and two years after operation, and a 3rd was coping adequately with all her housework until the time of her sudden death seventeen months after operation. The other 4 patients are still in hospital but are more generally sociable and active With the major symptoms of their illness removed they enjoy a happier and much less disturbed existence Case 9 illustrates the type of improvement seen in this group

Case 9—A single woman aged 60 had worked for one employer for thirty years She was always healthy until the outbreak of war In 1939 with the menopause she became depressed and developed ideas of reference of various kinds She heard voices giving her religious instructions. She thought her doctor was trying to influence her thoughts, and felt guilty of being unable to catch their religious significance Early in 1940 she left her employer suddenly and without warning and gave herself up to the police She declared that she was responsible for the war She was admitted to hospital under certificate and remained depressed and hallucinated for a year but after a second year she left the hospital Four years later she again had to be certified. Now she was actively hallucinated and had made various suicidal attempts saying that she preferred to die than to lead a wicked life She had a large amount of convulsion therapy with both leptazol and electricity but after four more years in hospital she remained just as hallucinated *profoundly depressed*, and actively suicidal. Her personality remained reasonably well preserved

After operation she seemed rather quiet and a little less depressed, and could be made cheerful and to smile more easily She said she felt happier She remained subdued but was no longer hallucinated or suicidal She continued to improve took an active interest in simple affairs about her and went out on visits frequently Clinically she is greatly improved but because of her age and friendlessness and the difficulty of getting her somewhere to go she has been unable to leave hospital.

Case 3 is also recorded for until the time of her sudden death, seventeen months after operation, she had exhibited a fairly typical pattern of improvement.

Case 3—A married woman, aged 40 had been a paranoid schizophrenic for nine years at the time of operation She had been hostile towards her husband and adopted son and was eventually certified because she was a danger to her husband who was an invalid. She was generally arrogant irresponsible querulous, and noisy; often she was negativistic. Sometimes she became violently hostile and aggressive She later became rambling and incoherent in her accounts of her persecution, and eventually talked of nothing else but her son's wrongdoings. She was quite without insight.

After operation she very soon became quieter and was composed and sensible The framework of delusions about her adopted son was still elicited on questioning but she no longer mentioned it spontaneously and this in her case represented a great change She would even inquire about him in a kindly way and no hostility was evident. Her husband was delighted ' with her During the next six months she continued to improve and became coöperative sociable and a very willing worker She was euphoric for a time and was then garrulous, without foresight and content to live for the moment After operation her delusions never again had any emotional force She needed no more sedative drugs She was discharged at six months and continued happily until her sudden death

UNCHANGED (5 CASES)

Of these 5 patients 4 (cases 2 8 11 and 20) had been schizophrenic for twelve eight two and four years and the 5th (case 16) had had severe agitation and depression for ten years They now show little change compared with their preoperative state However it should be noted that 4 of them made considerable temporary improvement after operation and for a much longer time than after any previous treatment but all relapsed three within two months of the operation, and 1 (see below) nine months after operation. 1 schizophrenic (case 8) is *still free from the violent behaviour and impulsiveness* exhibited preoperatively but his condition is otherwise unimproved and he cannot be regarded as having made any substantial gain

Case 11—A man aged 22 was discharged on psychiatric grounds from the R A F He had behaved oddly talked to himself and been very strange and solitary Later he became aggressive and resentful fought his adoptive father and smashed windows. He developed into a very noisy hallucinated schizophrenic abusive and threatening Often he was extremely aggressive and would mutter to himself and roll on the floor Some of the time his manner was euphoric and happy go lucky He had a long course of insulin but never went into coma, though he reached a dose of 270 units. He improved physically but not mentally He had also a course of electroconvulsive therapy and another of continuous narcosis with paraldehyde and hyoscine A preoperative electro encephalogram was abnormal suggesting a constitutional dysrhythmia with a psychomotor variant A pneumo-encephalogram was within normal limits

After operation he immediately became quieter rational and coöperative For a short time he was even lethargic. He was never incontinent, but he had an epileptic fit at one week and another at four months after operation. After a few weeks he had a few minor outbursts, but not approaching the preoperative ones in force In general he improved mentally and became well enough for discharge The improvement however only lasted until nine months after operation, when after an episode of window smashing he was readmitted and is now essentially the same as before operation.

Effect on Personality

In our experience to date this operation has proved relatively free from undesirable psychological complications. Sometimes there is undue apathy or lack of initiative sometimes slowness with apparent lack of energy sometimes facility or fatuity once we observed severe but temporary disinhibition of an unpleasant character—all changes seen after leucotomy but never so pronounced Standard intelligence tests do not reveal any *significant change in intellectual ability* We can thus fully agree with the experience of Scoville et al (1952) that the operation does not cause serious intellectual or temperamental damage and is to be ' recommended because of its nearly complete preservation of the personality

Rylander (1952) also discussing operations which involve isolation of the inferior surface of the lobe, has stated that in his experience undesirable personality changes are always minimal personality change which does occur is of the same type as after standard leucotomy but not so pronounced

Unwanted personality changes are common after standard leucotomy the actual incidence one attributes to this operation depends on the criteria one adopts but in a small number probably about 10% there are serious symptoms and disturbances of behaviour which give rise to most unpleasant and incapacitating post operative syndromes At the other extreme, after very small lesions, changes of this magnitude are never seen Scoville and his associates attribute this absence of all serious deficits after the orbital operation to the purely quantitative fact that only about a third of the frontal-lobe connections are interrupted Briefly, we have in our personal experience, for such a quantitative comparison, two other similarly studied series one of full standard leucotomy (Tow 1952), and one of anterior cingulectomy (Tow and Whitty 1953) in which less than 4 c cm of cortex suffers interference on each side The personality changes which we have observed after orbital leucotomy approximate in quantity to those in anterior cingulectomy, though they differ in quality We have consequently been impressed with the smallness of any personality deficiencies in this series compared with those resulting from the standard operation If there is a typical postoperative personality picture it is that of a generally quiet, placid, and—in the extreme—even timid personality with a possible slight blunting of comprehension or mental acuity Gross postoperative abnormalities in behaviour have not been seen

Other Changes

Behaviour —Before operation these patients almost all showed some kind of disturbed behaviour 11 were subject to the most violent and uncontrollable outbursts , and 8 others were either violent and aggressive at times or a great suicidal risk The effect of operation has been extremely satisfactory In over half the patients the disturbance of behaviour disappeared immediately after operation and has not returned , in the others the improvement was neither immediate nor dramatic, but behaviour was favourably affected in all

Sleep —In general this has improved 7 patients have shown very considerable improvement , 3 of these sleep well without aid, whereas before they regularly needed hypnotics

Weight —10 patients gained in weight, but some have now begun to lose weight again, and the residual gain at present is mostly only a few pounds 1 has gained 4 stone, and 2 more 2 stone each

Sedatives —Several of the patients need fewer drugs, such as hyoscine, 'Amytal,' and paraldehyde There has been some fluctuation, both before and after operation, in the need for heavy sedation, but at least half the patients need considerably less than preoperatively

Complications

Epilepsy —Of the 20 patients 2 have had epileptic fits after operation, but in neither have the attacks been frequent In 1 case the first fit took place eight weeks after operation, and over the next three years there were two further attacks at six months and nine months In the other case the patient showed a dysrhythmia suggesting epilepsy on the preoperative electro encephalogram , his first fit occurred a week after operation, and he had one more attack over the next two and a half years, at four months after operation So far, with the average follow up of two years, no patient has begun to have epileptic attacks for the first time after the early postoperative period The patients were not given prophylactic anticonvulsant therapy Electro encephalograms were made preoperatively and from one and a half to three years later in 15 of these patients, and no significant changes were seen

Incontinence has been minimal compared with its incidence after standard leucotomy 1 patient was regularly incontinent of urine for the first two weeks and was once incontinent of fæces , a 2nd patient was incontinent for five days , and 3 others had occasional incontinence during the first postoperative month , but in all the cases full control was re-established

Discussion

A large body of conservative psychiatric opinion accepts leucotomy as an available routine treatme Many feel that it is illogical but that circumstances for them to use it in certain cases in which experience h now shown that it yields an improvement otherw unobtainable The fact, however, that it may have some advantages over other empirical methods no reason why one should accept its disadvant unperturbed If in the absence of what may be rational methods—for appropriate cases—cerebral su gery is proving to be a valuable therapeutic approach, becomes more, rather than less, important to seek ope tions which do the greatest good and the least bad

With the current interest in this problem there ha come to be two distinct opinions one that the tot clinical change produced is proportionate simply to amount of cerebral tissue destroyed , and the the change is in some way related to the particular involved Evidence has accumulated on both The work of Meyer and McLardy has now yiel many valuable correlations , but there is still no clinical guide to what exactly should be cut in indi clinical syndromes There is, in fact, still no dec evidence about the relative merits and demerits of different incisions In practice there has developed an attitude of caution towards the major operation but with great uncertainty about what to use in its place The suggestion of Sargant and Slater (1948) is that where it is possible to conduct the operation in stages it is best to start anteriorly, a second and more posterior cut being possible if the first does not produce the desired effect Thinking on these lines, however, we suggest that it may be more informative to make the first incision in definitely selected part of the frontal lobe (so far as surgically possible) A suitable part is the whole of o surface We agree with the implication of Sargant Slater that, as a routine substitute for the major tion, it is not yet practicable to use anatomical v of very precise location However, an incision a the whole of one surface, and a standard leucotomy, more likely to result in two unequivocally discrete than is an attempt first to produce an anterior image the standard cut , and so in the long run such a may be more useful and informative

On balance, the effect of orbital leucotomy seems t be at least as good as that of standard leucotomy bu with fewer undesirable complications The results in typical but small group of cases compare well with clinical results after the standard operation There ha been no death due to the operation in this series, and th results so far indicate that there is far less likelihood any permanent physical complication or of any seri damage to the personality Although the patients in series were not all of the worst prognosis, the results very considerably better than could be expected other forms of treatment The numbers involved small, but half the patients with affective disorders recovered after illnesses with an average duration of te years The effect on violent behaviour has been extrem satisfactory Half the schizophrenics have improved, only a sixth have recovered The important however, is that whatever recovery has been obtaine takes place in the first few weeks or months , provided such a recovery lasts, this possibility, procuring early relief in an illness likely to last for year must always be an argument for the use of surger

The results in this series so far suggest that orbit leucotomy produces therapeutic results comparable those of prefrontal leucotomy but with much less person ality damage, and it seems to be worthy of further tri in some cases where relatively major surgery is thoug necessary for the treatment of mental illness In impu and violently disturbed active psychotics and in chron affective disorders with great tension and anxiety it may be the operation of first choice after all non surgical treatments have failed

Summary

The operation of orbital leucotomy is described It is an open operation and consists of a horizontal incision in the white matter just above the orbital cortex

Of 20 patients with various psychiatric disorders operated on two years ago 7 have recovered and 8 more have improved.

There was no death due to the operation

Because physical and psychological complications are minimal and beneficial effects are comparable with those of prefrontal leucotomy orbital leucotomy is recommended for trial particularly in patients with severe intractable tension and disturbed behaviour, as a common alternative to the standard operation

These patients were referred to us by Dr R W Armstrong, Dr John Duffield and Dr William Ogdon who have throughout the work helped in the assessment of results We thank Miss F M Taylor for performing the electro-encephalography; and Miss A. Arnott for the illustration. We are grateful to Dr R G McInnes and Dr Ian Skottowe for helpful criticism

This work was done under the direction of the late Sir Hugh Cairns, who performed all the early operations

PYREXIA IN THE PUERPERIUM

ROY M CALMAN
M.B Glasg
ASSISTANT DIRECTOR, BERNHARD BARON MEMORIAL RESEARCH LABORATORIES

JOHN GIBSON
M.R C.O G D C.H.
RESIDENT OBSTETRICIAN
QUEEN CHARLOTTE'S MATERNITY HOSPITAL, LONDON

IN 1950 it was decided to investigate the present causes of pyrexia in the puerperium Clinical observation had suggested that the present-day practice of obstetrics had altered the type and site of infections responsible for a rise of temperature in the puerperium from those commonly described in the textbooks In addition changing conditions had led to some inaccuracies in the returns made of notifiable pyrexia and a false over all picture was being obtained The unsatisfactory position regarding notification has been clearly stated by Gordon (1951)

It was also felt that a careful analysis of all the cases of pyrexia in the puerperium during a definite period might provide a basis for the revision of the existing standard of notifiable pyrexia. During the period of the investigation however the regulations for notification of puerperal pyrexia were altered by the Ministry of Health and the present standard of a temperature of 100·4° F occurring once in the fourteen days after delivery was adopted How far the new standard is an improvement on the old and what might constitute a satisfactory alternative method of notification are discussed below

In any consideration of puerperal pyrexia it is helpful to understand how the present position of notification and the emphasis on uterine infection have arisen

Mayrhofer (1865) showed that the streptococcus was the probable cause of puerperal fever and Pasteur (1879) established beyond doubt the connection between this organism and death from puerperal sepsis The streptococcus continued to dominate the obstetric scene and notification of puerperal pyrexia was introduced in an attempt to check the spread of this infection

In 1932 Colebrook with his colleagues attacked the problem of streptococcal infection in midwifery and in the ensuing years published a series of papers emphasising the necessity for the control of throat carriers and the importance of detailed antiseptic technique in reducing the incidence of infection It was not until the classic paper of Lancefield and Hare (1935) that the significance of the group A streptococcus became apparent. The connection with erysipelas, scarlet fever and streptococcal tonsillitis became obvious, and the confusion caused by the presence in the vagina of relatively non pathogenic but hæmolytic streptococci of other groups was clarified

The use of 'Prontosil' in streptococcal infection was described by Domagk (1935) and its use in obstetrics was investigated by Colebrook in 1936 Since Colebrook and Kenny (1936) reported the successful treatment of streptococcal uterine infection the organism has lost much of its terror and with the discovery of penicillin sepsis has become a very rare cause of maternal death in this country

Arguments about pyrexia in the puerperium have waged since the days of White and Gordon in the late 18th century and there are many papers discussing the causes of pyrexia, notable contributions being those of Lea (1910), Little (1905) and Stander (1945) Two major points arise from the study of the historical background to this subject (1) emphasis was always on mortality and not morbidity and (2) organisms are mentioned which are not now regarded as normally pathogenic Relatively little attention was paid to the extragenital infections, and there is a dearth of new information available from the period following the work of Colebrook and his colleagues

It is well known that sepsis is virtually never a cause of maternal death at present in fact there has been only one such case (due to *Clostridium welchii*) in the last six years at this hospital, during which time some 15 000 patients have been delivered Nevertheless puerperal pyrexia remains a common cause of maternal morbidity and may lead to a longer stay in hospital In all that follows the difference between puerperal sepsis and puerperal pyrexia is important Confusion between these two still exists despite the fact that every book or paper emphasises the distinction It is puerperal pyrexia—a rise of temperature in the puerperium—with which we are dealing Puerperal sepsis or infection of the genital tract with pathogenic organisms will be seen from what follows to be much more uncommon

Investigation

All patients who in 1951 had a raised temperature were submitted to a full clinical examination and a high vaginal swab and a catheter specimen of urine were examined. This routine was practised whenever the temperature rose above 99·4°F on any occasion.

Bacteriological Methods

The methods by which these specimens were examined were as follows

On arrival in the laboratory the high vaginal swab was inoculated on two blood-agar plates and a direct film was stained by Gram's method. One blood-agar plate was incu bated aerobically, and the other anaerobically, for eighteen hours or, if necessary, forty eight hours, and the plates were then examined by standard methods (Gibson and Calman 1953) Organisms were picked off for special investigation when required, and provisional reports were issued at once The direct film was examined, and the amount of pus present was reported in addition to the presence of organisms

A sample from the cathether specimen of urine was centrifuged and its deposit examined, both a wet preparation and a gram stained film being used The spun deposit was cultured aerobically on blood agar and MacConkey's agar

Steps in Investigation

Every effort was made to give some guidance to the clinicians twenty-four hours after receipt of the specimens, so that isolation and other measures could be applied without delay, treatment was not delayed for bacteriological tests if it was thought to be urgent

The investigation fell into three parts (1) the whole of the group was reviewed, (2) an attempt was made to correlate these pyrexias with obstetrical manœuvres or other occurrences which are supposed to cause pyrexia, and (3) only those cases were considered in which a notifiable temperature of 100 4° F was reached

So that no case should be missed, all the notes were examined by the records officer, who selected all those in which a temperature of 99°F had been charted, all patients who had a known rise in temperature in the twenty four hours before delivery being excluded from the survey This produced the large number of 1423 cases out of 2701 patients delivered in 1951 All these were next checked against the laboratory records to trace any reports which had been incorrectly filed The whole group were then examined in detail, and 469 were rejected because they had not reached the standard of 99 4°F This left 954 cases in which the temperature had been above this figure, each case being scrutinised and an attempt being made to group them as either purely obstetrical or medical conditions occurring without particular relation to the pregnancy, the bacteriological reports being used to check the clinical findings

General Findings

The 954 cases were divided into the following groups

	No of cases
Pyrexia of no significance	499
Genital tract	141
Urinary	132
Breast	48
Non-obstetric	71
No cause found	63

The 499 cases of pyrexia of no significance consisted mainly of patients whose pyrexia, often in the day following delivery, was slight and not maintained In these cases also the pyrexia settled within twenty-four hours without treatment, symptoms, or positive findings In contradistinction the 63 cases in which no cause was found consisted of patients who had a definite and continued pyrexia, but in whom clinical and bacteriological investigation yielded no result This group also contained those cases in which bacteriological examination was inadvertently omitted

Other difficulties arose in classifying these cases

(1) The same pathogen was sometimes isolated from both high vaginal swab and catheter specimen of urine In these cases the presence of a considerable number of pus cells in either site was taken as the deciding factor

(2) In some cases the temperature was high but the bacteriological and clinical findings were not substantially significant To avoid classifying such cases on inadequate grounds they were labelled "no cause found"

(3) In some patients a pathogenic organism was isolated but with a minimal rise of temperature, these were reluctantly placed in the relevant group

Genital tract Infections

The decision to include cases in this category was made on an assessment of clinical and bacteriological findings taken together The presence of clinical signs, of known pathoge organisms, and of intracellular organisms in the purul discharge, and the response to treatment were all us to decide whether a case should be placed in this cat or not For instance, the one case in which *Staphyl coccus albus* is listed as the causal organism was d on definite clinical evidence and response to treatment

The organisms isolated from the high vaginal swa in the 141 cases of genital-tract infection were follows

Organism	*No of*
Anaerobic streptococcus	48 (34 0%)
Aerobic non hæmolytic streptococcus	19 (13 5%)
Staph albus	1 (<1·0%)
Bact coli	8 (6 0%)
Strep viridans	11 (8 0%)
Diphtheroids	1 (<1·0%)
Diphtheroids and *Bact coli*	2 (1 5%)
Diphtheroids and *Staph albus*	3 (2 0%)
Staph aureus	23 (16·4%)
Cl. welchii	1 (<1·0%)
β hæmolytic streptococcus group C	1 (<1 0%)
β hæmolytic streptococcus group D	2 (1 5%)
β hæmolytic streptococcus group G	8 (6 0%)
β hæmolytic streptococcus (ungroupable)	8 (6 0%)
Gonococcus	1 (<1 0%)
Strep viridans and *Bact coli*	1 (<1 0%)
Anaerobic streptococcus and *Staph. aureus*	1 (<1·0%)
No significant organism isolated	2 (1 5%)
Total	141

The distribution of organisms differs from that reported by other workers (Little 1905, Stander 1945) Th notable feature is the complete absence of group A hæmolytic streptococci, recently, however, an outbreak of infection due to this organism occurred in this hospit (Gibson and Calman 1953) The importance of anaerob streptococci is clear, and *Staph aureus* seems to be frequent pathogen, this later organism appears to b responsible for more infections than previously occurs often in various types of infection throughout th hospital Many of the other organisms reported may fact be saprophytic and not related to infection

Urinary tract Infections

The organisms isolated from 132 cases of urinar tract infection were as follows

Bact coli	96
Strep fæcalis	11
Mixed growth	18
Staph aureus	5
Paracolon	2

In assessing such cases more importance was placed on th presence or absence of pus than on isolation of th organism alone, and in all these cases pus cells wer present in fair numbers

The organisms isolated from the urine show th expected preponderance of coliforms The place of the fæcal streptococcus as an infecting organism in th urine is not entirely clear, because the urine can easil be contaminated with this organism while the is being collected Nevertheless in some cases strept cocci are seen alone together with pus cells and m be regarded as causing the infection On the other hand the occasional case in which *Staph aureus* was isolat is in keeping with the frequency with which the organis is being found in other sites

Breast Abscess

The criteria for accepting the breasts as a cause o pyrexia were strict, engorgement alone being accepte in only 2 cases out of 48, in both of these there were n other positive findings and the temperature sett without treatment at the same time as the engorge ment subsided In 13 cases pus was obtained eith by incision or by expression *Staph aureus* being causal organism in each case In the remaining 3 cases the mastitis was definite and subsided with anti biotic treatment

Non-obstetric Causes

In this group were placed such things as minor seps excluding that of the genital tract, and general medic conditions, they were as follows

	No of cases
Thrombosis and hæmatoma	19
Chest	23
Upper respiratory tract	24
Minor sepsis	3
Enteritis	2
Total	71

Of the patients with infections of the chest and respiratory tract 14 had undergone general anæsthesia this represents only 0·5% of the patients anæsthetised during the year

No Cause Found

There remained a substantial group of 63 cases (14%) in which we were unable to discover any cause for the rise in temperature

Correlation of Pyrexia with Previous Events

The second part of this investigation was an attempt to correlate the pyrexia with any predisposing cause such as obstetric manœuvres and blood loss

Infections of Genital Tract

92 cases (65%) had experienced some interference or tissue damage the manœuvres performed in these cases were as follows

	No. of cases
Episiotomy	42
Tears	36
Manual removal	5
Cæsarean section	9

This left 49 cases (35%) in which delivery was spontaneous without tears or interference We were unable *to show any clear relationship to delivery by forceps* the 77 cases in which there were tears and episiotomies containing almost equal numbers of spontaneous and forceps deliveries (In 95% of all forceps deliveries an episiotomy was done)

Manual Removal

This was done on 52 occasions in the year 8 of these patients had a rise in temperature 2 being due to urinary infections in the remaining 6 the genital tract appeared to be the site of infection, the infecting organisms being *Cl welchii* anaerobic streptococcus, *Bact coli* (2 cases) *Staph albus* and *Strep viridans*

Cæsarean Section

After 39 of the 117 such operations there was a rise in temperature to 99·4°F the causes of the pyrexia being as follows :

	No. of cases
Genital infection	9
Urinary	8
Thrombosis and hæmatoma	3
Medical	1
Temp. 1st 24 hours only	9
No cause found	9

Blood-loss

During the year under consideration 111 cases of postpartum hæmorrhage occurred, and of these 35 reached the 99 4°F level of pyrexia ; in addition 4 other patients with this pyrexia had an antepartum hæmorrhage *These figures showed no greater incidence* of pyrexia than the number that would be expected in 111 deliveries since about a third of all the patients delivered during the year reached this standard of pyrexia (see above) We were therefore unable to show any close relationship between blood loss and pyrexia

Comments

In the same way we attempted to relate infections of the urinary tract to obstetric manœuvres but the results were inconclusive, except as regards cæsarean section in which group 20% of the pyrexias were due to infections of the urinary tract.

The rôle of trauma in predisposing to infection has not been established in our cases, but this may have been influenced by the fact that all the patients were treated in hospital and that usually we did not have any severe infections within this period Whether the effect of trauma on the infection rate would have been greater if treatment of shock and hæmorrhage had been less adequate is an open question

In considering the bacteriology of genital tract infection it was remarked that many of the organisms might be saprophytic We felt that in many instances organisms were isolated from the high vaginal swab which can be shown to be present in the vagina of normal patients and cannot be *regarded as always pathogenic* when isolated from a patient with pyrexia In some cases however organisms of low virulence can cause infection in damaged tissue

This has led us to investigate afresh the whole question of uterine and high vaginal swabs as a method of diagnosis Previous work on the interchangeability of these methods has largely been related to infections with the hæmolytic streptococcus, and with the changes in emphasis which we have found the situation has altered considerably The results of the further investigation although incomplete throw considerable doubt on the value of the high vaginal swab in non-streptococcal cases of pyrexia

It does seem however, that the cases which have clinical signs of uterine infection are also those in which the bacteriological findings are unequivocal ; and, *further that many cases considered to have low grade* uterine infection on the results of high vaginal swab examination do not in fact have more than local trauma and absorption of autolysed tissue as a cause of their pyrexia

Notifiable Pyrexia

The third part of our investigation concerned those cases in which the new Ministry of Health standard of 100 4°F was reached. This occurred in 188 cases (7% of the year s total) as follows

	No of cases
Urinary tract	55 (29%)
Genital tract	49 (26%)
Non-obstetric	30 (16%)
Breast	21 (11%)
No cause	33 (17%)

It is interesting to compare this distribution with Gibberd s (1947) classification of 378 cases of notifiable pyrexia at Guy s Hospital in 1928–37

Total number of cases	*188*	*378*
Genital	26%	54%
Urinary	29%	18%
Breast	11%	7%
Respiratory and other infections	16%	21%
No cause	17%	—

There are two obvious major differences in the present series : (1) the decrease in genital infection and the corresponding relative increase in urinary infection ; and (2) the presence of a ' no cause found ' category This classification is necessary because of two factors (*a*) pyrexia occurring once only requiring notification, and (*b*) pyrexia within twenty four hours of delivery being notifiable In the past few years the rate of notifiable pyrexia (according to the old standard) in this hospital and other similar units has stood at about 3% judged by the published reports The notification rate will be at least doubled by the new standard the publication of figures resulting from the increased rate of notification may produce unreliable or even alarming appearances Of the 188 cases of notifiable pyrexia listed above only 26% were due to infections of the genital tract and of them more than half were clinically mild , hence perhaps 10% of all notifiable cases (18 cases in the year) had a moderate or severe genital infection As regards cæsarean section 22 cases out of 117 (19%) reached the new notifiable temperature in 8 of these cases the pyrexia occurred only in the twenty four hours after operation and in 2 others the pyrexia occurred once only without positive findings Therefore in 10 out of 22 notifiable cases the temperature settled without treatment or positive findings. (Of the remaining 12 patients only 3 appeared seriously ill.)

Conclusion

We feel that, if an alternative can be devised which would involve notification of cases of true genital-tract infection only, this would encourage notification of exactly those cases for which this procedure was devised The main object of notification is to bring infectious diseases under rapid control and to prevent their spread from patient to patient the only important cause of puerperal pyrexia which falls within the scope of this objective is infection of the uterus by hæmolytic streptococci belonging to Lancefield's group A We therefore suggest that the older practice of notifying cases of uterine infection rather than puerperal pyrexia should be restored Today general practitioners are accustomed to cooperate with the Public Health Laboratory Service in the control of infectious diseases—e g, diphtheria—and it might be that confining notification to proved streptococcal cases would give more evidence of epidemiologic d value than does the present system

If, on the other hand, this is felt to be impracticable, we think that notification as a whole should be abandoned We do not consider that further adjustments in the level of pyrexia would serve any useful purpose

Summary

All cases in which there was a rise of temperature in the puerperium during 1951 at Queen Charlotte's Hospital are reviewed and classified according to cause and relationship to obstetric manœuvres

The incidence of notifiable pyrexia is discussed and the present standard considered

We wish to thank Dr John Murray and Mr G F Gibberd for valuable advice, and the staff of the records department, especially Miss Jacobson, the records officer, for the initial separation of the pyrexial cases

THE neurological manifestations of cervical spondylosis are described in detail by Brain et al (1952) in a comprehensive article in which they report medical and surgical experience with 45 patients of their own These workers draw attention to the extraordinary variations in the mode of presentation of the disorder

In a large proportion of cases of cervical spondylosis sensory symptoms and signs differentiate the disorder clearly from any form of motor-neurone disease That confusion can arise, however is shown by Brain's allusion to cases in which amyotrophic lateral sclerosis had previously been diagnosed. Failure of the condition to progress led to subsequent review of these patients, and they were found to have cervical spondylosis.

We have recently become aware that cervical spondylosis may also produce a syndrome closely resembling progressive muscular atrophy with wasting, weakness and fibrillation of the upper limbs, yet clearly [illegible] from the painful amyotrophy with associated sensory signs which results from the traumatically induced lateral protrusion of cervical discs described by S[illegible] and Murphy (1943) and Spurling and Scoville (1944)

The cases described here show the close clinical resemblance which may exist between certain manifestations of cervical spondylosis and those of motor neurone disease, both in its guise of amyotrophic lateral sclerosis and in that of progressive muscular atrophy

Cases Simulating Amyotrophic Lateral Sclerosis

Case 1 —A man, aged 62, was first seen in August, 1941, at the age of 50 At that time he gave six months' history of stiffness in the right leg, followed within a few weeks by stiffness in the right hand, weakness of both legs, and a tendency to spontaneous clonus on sitting down

Examination at that time revealed wasting, weakness, and fibrillation of the small muscles of the hand, right plantar response doubtfully extensor, right arm jerks brisker than left, and no sensory loss On this evidence motor neurone disease was diagnosed, but the patient was not seen again until July, 1952, when he said that his leg stiffness had remained more or less static during the intervening period, but that in July, 1951, the disability had begun to increase, and in addition he had noted some weakness and wasting of the right forearm and hand

Re examination revealed that, in addition to his spastic paraparesis and extensor plantar responses, he had developed wasting of the right arm, with fasciculation in the proximal muscles on both sides All his tendon reflexes were brisk. There was still no sensory loss In December, 1952, he was seen again and mentioned for the first time a sensation of pricking on the index finger of the right hand On this occasion a new sign of impairment to pinprick over the right index and up the medial section of the forearm was noted.

Radiography of the cervical spine revealed a slight diminution of the C5–C6 disc space, and some osteophytes (fig 1) On flexion and extension movement was normal at all levels

Other investigations —The cerebrospinal fluid (C S.F) under a pressure of 120 mm H_2O, dynamics normal, contained protein 35 mg per 100 ml, and no increase of globulin A Lange test was normal Myelography (fig 2) revealed disc protrusion not only at C5–C6 but also at C3–C4

Diagnosis —The lengthy duration of this condition, coupled with the development of sensory symptoms and signs after so long an interval, seemed to make the original diagnosis of motor neurone disease untenable, and the myelographic findings supported the view that the symptoms were due to cervical spondylosis

Treatment —A leather collar was fitted, and when he last seen the patient said that there had been some improvement in the power of his right arm and hand though the signs were otherwise unchanged.

Case 2.—A male railway worker, aged 57, was seen on March 7, 1952, complaining of stiffness of the legs and of power and control of the right hand and arm Two years earlier he had experienced dragging, first of the right leg and soon after of the left After twelve months his right hand became stiff, weak, and uncontrollable, and he had noted weakness of the muscles of the shoulder and arm. Though conscious of the flickering in the wasted muscles he had at no time had any pain or paræsthesiæ

Examination revealed blood pressure 230/140 mm Hg heart, lungs, abdomen, and cranial nerves normal, wasting of muscles of shoulder girdle bilaterally, more pronounced on the right widespread fasciculation in all the affected muscles, both legs spastic tendon reflexes very brisk arms and legs, abdominal reflexes absent, plantar [illegible] extensor, sensation normal except for diminished vibration sense in the legs

Investigations —The Wassermann reaction was negative in blood and C S F The C S F contained 2 cells per c mm and protein 55 mg per 100 ml A blood count and a fractional

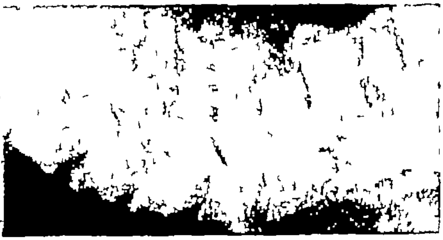

Fig 1—Case 1 : slight diminution of C5–C6 intervertebral disc space with formation of osteophytes.

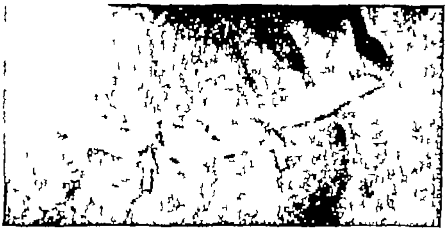

Fig 2—Case 1 : interruption of myodil pattern at C3–C4 and C5–C6 intervertebral disc spaces. Patient is prone.

test meal were normal Radiography of the cervical spine showed evidence of osteo-arthritic change Cisternal myelography revealed subluxation at C3–C4 with a break in the Myodil column A more obvious defect appeared at C5–C6

Diagnosis and treatment—On the radiological evidence the clinical temptation to attach a diagnosis of amyotrophic lateral sclerosis was easily resisted A leather collar was applied and there has been some subjective improvement in the patient's condition in the past twelve months although the signs remain unchanged There is still no pain and still no sensory change.

Case 3.—A man aged 56 was first seen in June, 1951 Three years earlier he had experienced progressive weakness of the legs. After eighteen months he noticed in addition that there was an intermittent flickering of the small muscles of the hand followed after an interval of a few months by some wasting Investigation at another hospital at this stage led to the diagnosis of motor neurone disease eminently justifiable on the evidence then available Shortly before being seen in the *neurological clinic*, however he had experienced intermittent deadness of the legs.

Examination revealed wasting and fasciculation of the transverse head of the left adductor pollicis muscle a spastic paresis of both legs and a generalised hyper reflexion. The plantar responses were extensor No superficial sensory loss was detected but there was some diminution of vibration sense in the legs. The new complaint of a sense of deadness led to his admission to hospital and on admission two months after the initial examination he had developed, in addition to his motor signs a rather patchy impairment of superficial sensation in the lower limbs His vibration sense was definitely impaired, and he made a few mistakes in position sense in the toes.

Investigations—A blood-count was normal. The Wassermann reaction was negative in the blood and the C.S.F A fractional test meal was normal The C.S.F contained 1 cell *per c.mm protein 80 mg per 100 ml* and a small amount of globulin. A Lange test was normal Radiography of the cervical spine showed pronounced degeneration of discs and osteo-arthritic lipping Cervical myelography showed indentation of the myodil pattern at C3–C4 C4–C5 C5–C6, and C6–C7 with subluxation at C3–C4

Treatment—A leather collar was fitted, and with this the patient appeared to improve a little at first In March, 1952 however he was readmitted because he said that the numbness in his legs had become more severe and he had begun to have some precipitancy of micturition. Clinical re-examination revealed a very slight increase in his signs, sensory and motor After consultation with Mr Richard Johnson skull traction was applied as a prelude to operation The patient then developed bilateral femoral thrombosis and subsequent pulmonary infarction, and his subsequent course has been a steady battle against the increasing disability resulting from the enforced immobility His collar was reapplied, with great benefit to the fasciculation and wasting in the left hand, which now appears almost normal

Case 4.—A woman, aged 60 was seen on Jan. 30 1953 complaining of weakness of the arms and stiffness of the legs Fourteen months earlier she had fallen in the street but suffered no obvious ill effects. Four months after this however she began to have stiffness in the legs, and within another month she experienced great difficulty in using her hands and arms for such activities as combing her hair and using a knife and fork. The symptoms had progressed steadily, until at the time of examination she was bedridden. There had been no pain and no other sensory symptoms She had been seen at another hospital, where amyotrophic *sclerosis had been diagnosed*

Examination showed profound wasting and weakness of the proximal muscles of the arm with slight wasting and weakness of the forearm and hand. There was intermittent fascicular twitching of all these muscles. The legs were spastic. All the tendon jerks were brisk. The plantar reflexes were extensor Vibration sense was absent in the legs; sensation otherwise normal

Investigations—A blood-count was normal The Wassermann reaction was negative The C.S.F contained 1 cell per c.mm. and protein 50 mg per 100 ml Radiography of the cervical spine showed cervical spondylosis with narrowing of disc spaces C4–C5 C5–C6 and C6–C7 and subluxation at C3–C4 Cervical myelography showed indentations in the myodil column at C4–C5 C5–C6, and C6–C7 interspaces

Cases Simulating Progressive Muscular Atrophy

Case 5—A bus-driver aged 59 was seen on Aug 17 1951 complaining of weakness, wasting and twitching of the muscles of the right arm Six months earlier he had noted flickering and jumping of the muscles of the right arm and forearm, at times so violent as to awaken his wife at night Two months later he developed difficulty in pulling the steering wheel of his bus round for a right-hand turn, and these symptoms steadily progressed. At no time had he *experienced any pain or paræsthesiæ*

Examination revealed that abnormalities were confined to the right arm and comprised weakness and wasting of all the muscles of the arm forearm and shoulder particularly of the extensors of the wrist. Coarse fasciculation was noted in all the affected muscles, but mostly in biceps and in the extensors of the wrist. The tendon reflexes were a little brisker in the right arm There was no sensory loss

Investigations—A full blood-count was normal The C.S.F was under a pressure of 120 mm H_2O dynamics normal and contained 1 lymphocyte per c.mm., protein 35 mg per 100 ml and no increase of globulin. A Lange test was normal. The Wassermann reaction was negative in blood and C.S.F Radiography of the cervical spine showed disc degeneration with osteo-arthritis in all the lower cervical segments as was also shown by cervical myelography (fig 3) there being a definite break in the myodil at C4–C5 disc space,

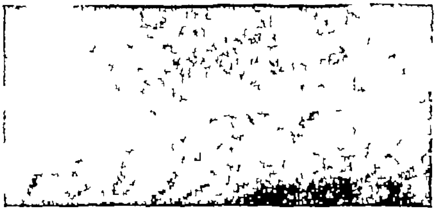

Fig 3—Case 5 : abnormality of C4–C5 C5–C6 and C6–C7 intervertebral disc spaces. In myodil pattern there is only a trickle of myodil lying in the left lateral gutter compared with good filling above and below lesion. Patient is prone

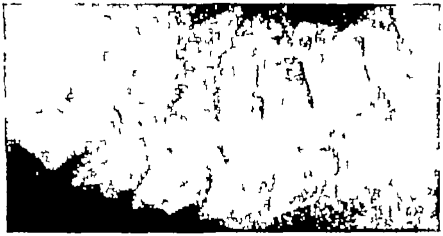

Fig. 1—Case 1: slight diminution of C5–C6 intervertebral disc space with formation of osteophytes.

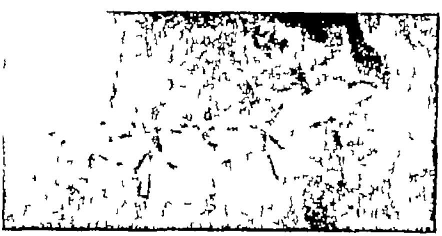

Fig 2—Case 1: interruption of myodil pattern at C3–C4 and C5–C6 intervertebral disc spaces. Patient is prone.

test-meal were normal Radiography of the cervical spine showed evidence of osteo-arthritic change Cisternal myelography revealed subluxation at C3–C4, with a break in the 'Myodil' column A more obvious defect appeared at C5–C6

Diagnosis and treatment—On the radiological evidence the clinical temptation to attach a diagnosis of amyotrophic lateral sclerosis was easily resisted A leather collar was applied and there has been some subjective improvement in the patient's condition in the past twelve months although the signs remain unchanged. There is still no pain and still no sensory change.

Case 3.—A man, aged 56, was first seen in June 1951 Three years earlier he had experienced progressive weakness of the legs. After eighteen months he noticed in addition that there was an intermittent flickering of the small muscles of the hand followed after an interval of a few months by some wasting Investigation at another hospital at this stage led to the diagnosis of motor neurone disease eminently justifiable on the evidence then available. Shortly before being seen in the neurological clinic however he had experienced intermittent "deadness" of the legs.

Examination revealed wasting and fasciculation of the transverse head of the left adductor pollicis muscle, a spastic paresis of both legs and a generalised hyper-reflexion. The plantar responses were extensor No superficial sensory loss was detected but there was some diminution of vibration sense in the legs. The new complaint of a sense of deadness led to his admission to hospital and on admission two months after the initial examination he had developed in addition to his motor signs a rather patchy impairment of superficial sensation in the lower limbs. His vibration sense was definitely impaired, and he made a few mistakes in position sense in the toes.

Investigations—A blood-count was normal. The Wassermann reaction was negative in the blood and the C.S.F A fractional test-meal was normal. The C.S.F contained 1 cell per c.mm. protein 80 mg per 100 ml., and a small amount of globulin. A Lange test was normal. Radiography of the cervical spine showed pronounced degeneration of discs and osteo-arthritic lipping Cervical myelography showed indentation of the myodil pattern at C3–C4 C4–C5 C5–C6 and C6–C7 with subluxation at C3–C4.

Treatment.—A leather collar was fitted, and with this the patient appeared to improve a little at first. In March, 1952 however he was readmitted because he said that the numbness in his legs had become more severe and he had begun to have some precipitancy of micturition. Clinical re-examination revealed a very slight increase in his signs, sensory and motor After consultation with Mr Richard Johnson skull traction was applied as a prelude to operation The patient then developed bilateral femoral thrombosis and subsequent pulmonary infarction, and his subsequent course has been a steady battle against the increasing disability resulting from the enforced immobility His collar was reapplied, with great benefit to the fasciculation and wasting in the left hand which now appears almost normal

Case 4.—A woman aged 60 was seen on Jan 30 1953 complaining of weakness of the arms and stiffness of the legs. Fourteen months earlier she had fallen in the street but suffered no obvious ill effects Four months after this however she began to have stiffness in the legs, and within another month she experienced great difficulty in using her hands and arms for such activities as combing her hair and using a knife and fork. The symptoms had progressed steadily until at the time of examination she was bedridden There had been no pain and no other sensory symptoms. She had been seen at another hospital, where amyotrophic sclerosis had been diagnosed

Examination showed profound wasting and weakness of the proximal muscles of the arm, with slight wasting and weakness of the forearm and hand. There was intermittent fascicular twitching of all these muscles. The legs were spastic. All the tendon jerks were brisk. The plantar reflexes were extensor Vibration sense was absent in the legs; sensation otherwise normal

Investigations—A blood-count was normal The Wassermann reaction was negative. The C.S.F contained 1 cell per c.mm. and protein 50 mg per 100 ml Radiography of the cervical spine showed cervical spondylosis with narrowing of disc spaces C4–C5 C5–C6 and C6–C7 and subluxation at C3–C4 Cervical myelography showed indentations in the myodil column at C4–C5 C5–C6 and C6–C7 interspaces

Cases Simulating Progressive Muscular Atrophy

Case 5—A bus-driver aged 39 was seen on Aug 17 1951 complaining of weakness, wasting and twitching of the muscles of the right arm Six months earlier he had noted flickering and jumping of the muscles of the right arm and forearm, at times so violent as to awaken his wife at night. Two months later he developed difficulty in pulling the steering wheel of his bus round for a right-hand turn, and these symptoms steadily progressed At no time had he experienced any pain or paræsthesiæ

Examination revealed that abnormalities were confined to the right arm and comprised weakness and wasting of all the muscles of the arm forearm, and shoulder particularly of the extensors of the wrist Coarse fasciculation was noted in all the affected muscles, but mostly in biceps and in the extensors of the wrist The tendon reflexes were a little brisker in the right arm There was no sensory loss.

Investigations—A full blood-count was normal. The C.S.F was under a pressure of 120 mm H_2O dynamics normal and contained 1 lymphocyte per c.mm. protein 35 mg per 100 ml and no increase of globulin. A Lange test was normal. The Wassermann reaction was negative in blood and C.S.F Radiography of the cervical spine showed disc degeneration with osteo-arthritis in all the lower cervical segments as was also shown by cervical myelography (fig 3) there being a definite break in the myodil at C4–C5 disc space,

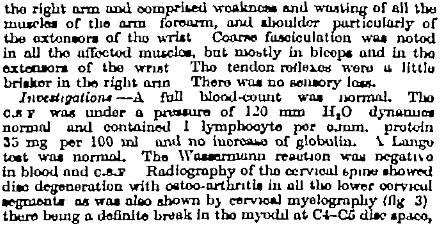

Fig. 3—Case 5: abnormality of C4–C5 C5–C6 and C6–C7 intervertebral disc spaces. In myodil pattern there is only a trickle of myodil lying in the left lateral gutter compared with good filling above and below lesion. Patient is prone.

Conclusion

We feel that, if an alternative can be devised which would involve notification of cases of true genital-tract infection only, this would encourage notification of exactly those cases for which this procedure was devised The main object of notification is to bring infectious diseases under rapid control and to prevent their spread from patient to patient, the only important cause of puerperal pyrexia which falls within the scope of this objective is infection of the uterus by hæmolytic streptococci belonging to Lancefield's group A We therefore suggest that the older practice of notifying cases of uterine infection rather than puerperal pyrexia should be restored Today general practitioners are accustomed to cooperate with the Public Health Laboratory Service in the control of infectious diseases—e g, diphtheria—and it might be that confining notification to proved streptococcal cases would give more evidence of epidemiological value than does the present system

If, on the other hand, this is felt to be impracticable, we think that notification as a whole should be abandoned We do not consider that further adjustments in the level of pyrexia would serve any useful purpose

Summary

All cases in which there was a rise of temperature in the puerperium during 1951 at Queen Charlotte's Hospital are reviewed and classified according to cause and relationship to obstetric manœuvres

The incidence of notifiable pyrexia is discussed and the present standard considered

We wish to thank Dr John Murray and Mr G F Gibberd for valuable advice, and the staff of the records department, especially Miss Jacobson, the records officer, for the initial separation of the pyrexial cases

THE neurological manifestations of cervical spondylosis are described in detail by Brain et al (1952) in a comprehensive article in which they report medical and surgical experience with 45 patients of their own These workers draw attention to the extraordinary variations in the mode of presentation of the disorder

In a large proportion of cases of cervical spondylosis sensory symptoms and signs differentiate the disorder clearly from any form of motor-neurone disease That confusion can arise, however, is shown by Brain's allusion to cases in which amyotrophic lateral sclerosis had previously been diagnosed Failure of the condition to progress led to subsequent review of these patients, and they were found to have cervical spondylosis

We have recently become aware that cervical spondylosis may also produce a syndrome closely resembling progressive muscular atrophy with wasting, weakness, and fibrillation of the upper limbs, yet clearly differing from the painful amyotrophy with associated sensory signs which results from the traumatically induced lateral protrusion of cervical discs described by Semmes and Murphy (1943) and Spurling and Scoville (1944)

The cases described here show the close clinical resemblance which may exist between certain manifestations of cervical spondylosis and those of motor neurone disease, both in its guise of amyotrophic lateral sclerosis and in that of progressive muscular atrophy

Cases Simulating Amyotrophic Lateral Sclerosis

Case 1 —A man, aged 62, was first seen in August, 1941, at the age of 50 At that time he gave six months' history of stiffness in the right leg, followed within a few weeks by stiffness in the right hand, weakness of both legs, and a tendency to spontaneous clonus on sitting down

Examination at that time revealed wasting, weakness, and fibrillation of the small muscles of the hand, right plantar response doubtfully extensor, right arm jerks brisker than left, and no sensory loss On this evidence motor neurone disease was diagnosed, but the patient was not seen again until July, 1952, when he said that his leg stiffness had remained more or less static during the intervening period, but that in July, 1951, the disability had begun to increase, and in addition he had noted some weakness and w of the right forearm and hand.

Re examination revealed that, in addition to his spastic paraparesis and extensor plantar responses, he had developed wasting of the right arm, with fasciculation in the proximal muscles on both sides All his tendon reflexes were brisk There was still no sensory loss In December, 1952, he was seen again and mentioned for the first time a sensation of pricking on the index finger of the right hand On this occasion a new sign of impairment to pinprick over the index and up the medial section of the forearm was noted.

Radiography of the cervical spine revealed a slight diminution of the C5–C6 disc space, and some osteophytes (fig 1) On flexion and extension movement was normal at all levels

Other investigations —The cerebrospinal fluid (C S.F) was under a pressure of 120 mm H_2O, dynamics normal, and contained protein 35 mg per 100 ml, and no increase of globulin A Lange test was normal Myelography (fig 2) revealed disc protrusion not only at C5–C6 but also at C3–C4

Diagnosis —The lengthy duration of this condition, coupled with the development of sensory symptoms and signs after so long an interval, seemed to make the original diagnosis of motor neurone disease untenable, and the myelographic findings supported the view that the symptoms were due to cervical spondylosis

Treatment —A leather collar was fitted, and when he last seen the patient said that there had been some ment in the power of his right arm and hand, though the signs were otherwise unchanged.

Case 2 —A male railway worker, aged 57, was seen March 7, 1952, complaining of stiffness of the legs and l of power and control of the right hand and arm Two y earlier he had experienced dragging, first of the right leg and soon after of the left After twelve months his right hand became stiff, weak, and uncontrollable, and he had noted weakness of the muscles of the shoulder and arm. Though conscious of the flickering in the wasted muscles he had at no time had any pain or paræsthesiæ

Examination revealed blood pressure 230/140 mm Hg, heart, lungs, abdomen, and cranial nerves normal, wasting of muscles of shoulder girdle bilaterally, more pronounced on the right, widespread fasciculation in all the affected muscles, both legs spastic, tendon reflexes very brisk arms and legs, abdominal reflexes absent, plantar reflex extensor, sensation normal except for diminished vibr sense in the legs

Investigations —The Wassermann reaction was negative in blood and C S F The C S F contained 2 cells per c mm. and protein 55 mg per 100 ml A blood count and a fraction

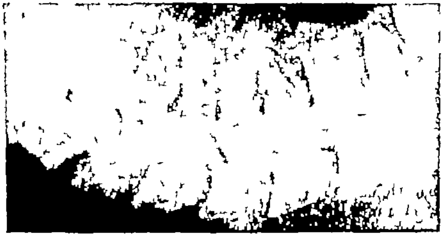

Fig. 1—Case 1: slight diminution of C5–C6 intervertebral disc space with formation of osteophytes.

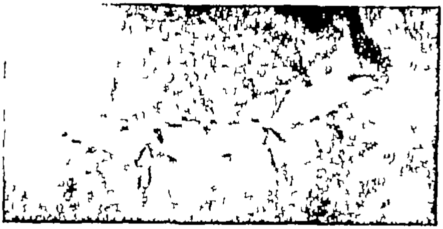

Fig 2—Case 1: interruption of myodil pattern at C3–C4 and C5–C6 intervertebral disc spaces. Patient is prone.

test-meal were normal *Radiography of the cervical spine* showed evidence of osteo arthritic change Cisternal myelography revealed subluxation at C3–C4 with a break in the 'Myodil column A more obvious defect appeared at C5–C6

Diagnosis and treatment.—On the radiological evidence the clinical temptation to attach a diagnosis of amyotrophic lateral sclerosis was easily resisted A leather collar was applied, and there has been some subjective improvement in the patient's condition in the past twelve months, although the signs remain unchanged. There is still no pain and still no sensory change

Case 3.—A man aged 56 was first seen in June 1951 Three years earlier he had experienced progressive weakness of the legs. After eighteen months he noticed in addition that there was an intermittent flickering of the small muscles of the hand, followed after an interval of a few months by some wasting Investigation at another hospital at this stage led *to the diagnosis of motor neurone disease, eminently* justifiable on the evidence then available Shortly before being seen in the neurological clinic, however he had experienced intermittent deadness of the legs.

Examination revealed wasting and fasciculation of the transverse head of the left adductor pollicis muscle a spastic paresis of both legs and a generalised hyper reflexion. The plantar responses were extensor No superficial sensory loss was detected but there was some diminution of vibration sense in the legs. The new complaint of a sense of deadness led to his admission to hospital, and on admission two months after the initial examination he had developed, in addition to his motor signs a rather patchy impairment of superficial sensation in the lower limbs. His vibration sense was definitely impaired, and he made a few mistakes in position sense in the toes.

Investigations—A blood count was normal. The Wassermann reaction was negative in the blood and the C.S.F. A fractional test-meal was normal. The C.S.F. contained 1 cell *per c.mm., protein 80 mg per 100 ml., and* a small amount of globulin. A Lange test was normal. Radiography of the cervical spine showed pronounced degeneration of discs and osteo-arthritic lipping Cervical myelography showed indentation of the myodil pattern at C3–C4 C4–C5 C5–C6 and C6–C7 with subluxation at C3–C4

Treatment.—A leather collar was fitted, and with this the patient appeared to improve a little at first. In March, 1952 however he was readmitted because he said that the numbness in his legs had become more severe and he had begun to have some precipitancy of micturition Clinical re-examination revealed a very slight increase in his signs, sensory and motor After consultation with Mr Richard Johnson skull traction was applied as a prelude to operation The patient then developed bilateral femoral thrombosis and subsequent pulmonary infarction, and his subsequent course has been a steady battle against the increasing disability resulting from the enforced immobility His collar was reapplied with great benefit to the fasciculation and wasting in the left hand which now appears almost normal.

Case 4.—A woman aged 60 was seen on Jan. 30 1953 complaining of weakness of the arms and stiffness of the legs Fourteen months earlier she had fallen in the street but suffered no obvious ill effects. Four months after this however she began to have stiffness in the legs, and within another month she experienced great difficulty in using her hands and arms for such activities as combing her hair and *using a knife and fork. The symptoms had progressed* steadily until at the time of examination she was bedridden. There had been no pain and no other sensory symptoms. She had been seen at another hospital, where amyotrophic sclerosis had been diagnosed.

Examination showed profound wasting and weakness of the proximal muscles of the arm with slight wasting and weakness of the forearm and hand. There was intermittent fascicular twitching of all these muscles. The legs were spastic. All the tendon jerks were brisk. The plantar reflexes were extensor Vibration sense was absent in the legs; sensation otherwise normal.

Investigations—A blood-count was normal The Wassermann reaction was negative The C.S.F. contained 1 cell per c.mm. and protein 50 mg per 100 ml Radiography of the cervical spine showed cervical spondylosis with narrowing of disc spaces C4–C5 C5–C6 and C6–C7 and subluxation at C3–C4 Cervical myelography showed indentations in the myodil column at C4–C5 C5–C6 and C6–C7 interspaces.

Cases Simulating Progressive Muscular Atrophy

Case 5—A bus-driver aged 50 was seen on Aug 17 1951 complaining of weakness, wasting and twitching of the muscles of the right arm. Six months earlier he had noted flickering and jumping of the muscles of the right arm and forearm, at times so violent as to awaken his wife at night. Two months later he developed difficulty in pulling the steering wheel of his bus round for a right-hand turn, and *these symptoms steadily progressed. At no time had he* experienced any pain or paræsthesiæ

Examination revealed that abnormalities were confined to the right arm and comprised weakness and wasting of all the muscles of the arm forearm and shoulder particularly of the extensors of the wrist Coarse fasciculation was noted in all the affected muscles but mostly in biceps and in the extensors of the wrist The tendon reflexes were a little brisker in the right arm. There was no sensory loss.

Investigations—A full blood-count was normal. The C.S.F. was under a pressure of 120 mm. H_2O dynamics normal and contained 1 lymphocyte per c.mm., protein 35 mg per 100 ml and no increase of globulin. A Lange test was normal The Wassermann reaction was negative in blood and C.S.F. Radiography of the cervical spine showed disc degeneration with osteo-arthritis in all the lower cervical segments, as was also shown by cervical myelography (fig 3) there being a definite break in the myodil at C4–C5 disc space

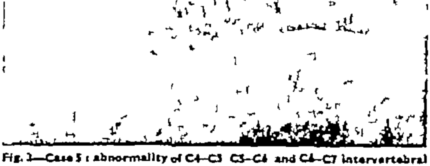

Fig. 3—Case 5: abnormality of C4–C5 C5–C6 and C6–C7 intervertebral disc spaces. In myodil pattern there is only a trickle of myodil lying in the left lateral gutter compared with good filling above and below lesion. Patient is prone.

Conclusion

We feel that, if an alternative can be devised which would involve notification of cases of true genital-tract infection only, this would encourage notification of exactly those cases for which this procedure was devised The main object of notification is to bring infectious diseases under rapid control and to prevent their spread from patient to patient the only important cause of puerperal pyrexia which falls within the scope of this objective is infection of the uterus by hæmolytic streptococci belonging to Lancefield's group A We therefore suggest that the older practice of notifying cases of uterine infection rather than puerperal pyrexia should be restored Today general practitioners are accustomed to cooperate with the Public Health Laboratory Service in the control of infectious diseases—e g, diphtheria—and it might be that confining notification to proved streptococcal cases would give more evidence of epidemiological value than does the present system

If, on the other hand, this is felt to be impracticable, we think that notification as a whole should be abandoned We do not consider that further adjustments in the level of pyrexia would serve any useful purpose

Summary

All cases in which there was a rise of temperature in the puerperium during 1951 at Queen Charlotte's Hospital are reviewed and classified according to cause and relationship to obstetric manœuvres

The incidence of notifiable pyrexia is discussed and the present standard considered

We wish to thank Dr John Murray and Mr G F Gibberd for valuable advice, and the staff of the records department, especially Miss Jacobson, the records officer, for the initial separation of the pyrexial cases

The neurological manifestations of cervical spondylosis are described in detail by Brain et al (1952) in a comprehensive article in which they report medical and surgical experience with 45 patients of their own These workers draw attention to the extraordinary variations in the mode of presentation of the disorder

In a large proportion of cases of cervical spondylosis sensory symptoms and signs differentiate the disorder clearly from any form of motor-neurone disease That confusion can arise, however, is shown by Brain's allusion to cases in which amyotrophic lateral sclerosis had previously been diagnosed Failure of the condition to progress led to subsequent review of these patients, and they were found to have cervical spondylosis

We have recently become aware that cervical spondylosis may also produce a syndrome closely resembling progressive muscular atrophy with wasting, weakness, and fibrillation of the upper limbs, yet clearly differing from the painful amyotrophy with associated sensory signs which results from the traumatically induced lateral protrusion of cervical discs described by Semmes and Murphy (1943) and Spurling and Scoville (1944)

The cases described here show the close clinical resemblance which may exist between certain manifestations of cervical spondylosis and those of motor neurone disease, both in its guise of amyotrophic lateral sclerosis and in that of progressive muscular atrophy

Cases Simulating Amyotrophic Lateral Sclerosis

Case 1 —A man, aged 62, was first seen in August, 1941, at the age of 50 At that time he gave six months' history of stiffness in the right leg, followed within a few weeks by stiffness in the right hand, weakness of both legs, and a tendency to spontaneous clonus on sitting down

Examination at that time revealed wasting, weakness, and fibrillation of the small muscles of the hand, right plantar response doubtfully extensor, right arm jerks brisker than left, and no sensory loss. On this evidence motor neurone disease was diagnosed, but the patient was not seen again until July, 1952, when he said that his leg stiffness had remained more or less static during the intervening period, but that in July, 1951, the disability had begun to increase, and in addition he had noted some weakness and wasting of the right forearm and hand.

Re examination revealed that, in addition to his spastic paraparesis and extensor plantar responses, he had developed wasting of the right arm, with fasciculation in the proximal muscles on both sides All his tendon reflexes were brisk. There was still no sensory loss In December, 1952, he was seen again and mentioned for the first time a sensation of pricking on the index finger of the right hand On this occasion a new sign of impairment to pinprick over the right index and up the medial section of the forearm was noted.

Radiography of the cervical spine revealed a slight d[illegible]tion of the C5–C6 disc space, and some osteophytes (fig 1) On flexion and extension movement was normal at all levels

Other investigations —The cerebrospinal fluid (C S F) was under a pressure of 120 mm. H_2O, dynamics normal, it contained protein 35 mg per 100 ml, and no increase [illegible] globulin. A Lange test was normal Myelography (fig 2) revealed disc protrusion not only at C5–C6 but also at C3–C4

Diagnosis —The lengthy duration of this condition, coupled with the development of sensory symptoms and signs after so long an interval, seemed to make the original diagnosis of motor neurone disease untenable, and the myelographic findings supported the view that the symptoms were due to cervical spondylosis

Treatment —A leather collar was fitted, and when he was last seen the patient said that there had been some improvement in the power of his right arm and hand, though the signs were otherwise unchanged

Case 2 —A male railway worker, aged 57, was seen on March 7, 1952, complaining of stiffness of the legs and [illegible] of power and control of the right hand and arm. Two years earlier he had experienced dragging, first of the right [illegible] and soon after of the left After twelve months his right hand became stiff, weak and uncontrollable, and he had noted weakness of the muscles of the shoulder and arm Though conscious of the flickering in the wasted muscles he had at no time had any pain or paræsthesiæ

Examination revealed blood pressure 230/140 mm Hg, heart, lungs, abdomen, and cranial nerves normal, wasting of muscles of shoulder girdle bilaterally, more pronounced on the right, widespread fasciculation in all the affected muscles, both legs spastic, tendon reflexes very brisk in arms and legs, abdominal reflexes absent, plantar reflexes extensor, sensation normal except for diminished v[illegible] sense in the legs

Investigations —The Wassermann reaction was negative [illegible] blood and C S F The C S F contained 2 cells per c mm and protein 55 mg per 100 ml A blood count and a fractional

Conclusion

We feel that, if an alternative can be devised which would involve notification of cases of true genital-tract infection only, this would encourage notification of exactly those cases for which this procedure was devised The main object of notification is to bring infectious diseases under rapid control and to prevent their spread from patient to patient the only important cause of puerperal pyrexia which falls within the scope of this objective is infection of the uterus by hæmolytic streptococci belonging to Lancefield's group A We therefore suggest that the older practice of notifying cases of uterine infection rather than puerperal pyrexia should be restored Today general practitioners are accustomed to coöperate with the Public Health Laboratory Service in the control of infectious diseases—e g, diphtheria—and it might be that confining notification to proved streptococcal cases would give more evidence of epidemiological value than does the present system

THE neurological manifestations of cervical spondylosis are described in detail by Brain et al (1952) in a comprehensive article in which they report medical and surgical experience with 45 patients of their own These workers draw attention to the extraordinary variations in the mode of presentation of the disorder

In a large proportion of cases of cervical spondylosis sensory symptoms and signs differentiate the disorder clearly from any form of motor-neurone disease That confusion can arise, however, is shown by Brain's allusion to cases in which amyotrophic lateral sclerosis had previously been diagnosed Failure of the c to progress led to subsequent review of these pati and they were found to have cervical spondylosis

We have recently become aware that cervical sp losis may also produce a syndrome closely resemb progressive muscular atrophy with wasting, weakn and fibrillation of the upper limbs, yet clearly di from the painful amyotrophy with associated ser signs which results from the traumatically lateral protrusion of cervical discs described by S and Murphy (1943) and Spurling and Scoville (1944)

The cases described here show the close cl resemblance which may exist between certain tations of cervical spondylosis and those of motor neurone disease, both in its guise of amyotrophic lateral sclerosis and in that of progressive muscular atrophy

Cases Simulating Amyotrophic Lateral Sclerosis

Case 1 —A man, aged 62, was first seen in August, 1941, at the age of 50 At that time he gave six months' of stiffness in the right leg, followed within a few weeks b stiffness in the right hand, weakness of both legs, and tendency to spontaneous clonus on sitting down

Examination at that time revealed wasting, weakness, fibrillation of the small muscles of the hand , right pl response doubtfully extensor , right arm jerks brisker than left , and no sensory loss On this evidence motor neurone disease was diagnosed, but the patient was not seen again until July, 1952, when he said that his leg stiffness had remained more or less static during the intervening period, but that in July, 1951, the disability had begun to increase, and in addition he had noted some weakness and wasting of the right forearm and hand

Re examination revealed that, in addition to his spastic paraparesis and extensor plantar responses, he had developed wasting of the right arm, with fasciculation in the proximal muscles on both sides All his tendon reflexes were brisk There was still no sensory loss In December, 1952, he was seen again and mentioned for the first time a sensation of pricking on the index finger of the right hand On this occasion a new sign of impairment to pinprick over the right index and up the medial section of the forearm was noted.

Radiography of the cervical spine revealed a slight diminution of the C5–C6 disc space, and some osteophytes (fig 1) On flexion and extension movement was normal at all levels

Other investigations —The cerebrospinal fluid (C S F) was under a pressure of 120 mm H_2O, dynamics normal, contained protein 35 mg per 100 ml , and no increase of globulin A Lange test was normal Myelography (fig revealed disc protrusion not only at C5–C6 but also at C3–C4

Diagnosis —The lengthy duration of this condition, with the development of sensory symptoms and signs so long an interval, seemed to make the original diagnosis of motor neurone disease untenable, and the myelographic findings supported the view that the symptoms were due to cervical spondylosis

Treatment —A leather collar was fitted, and when he was last seen the patient said that there had been some improvement in the power of his right arm and hand, though the signs were otherwise unchanged.

Case 2 —A male railway worker, aged 57, was seen on March 7, 1952, complaining of stiffness of the legs and loss of power and control of the right hand and arm Two y earlier he had experienced dragging, first of the right and soon after of the left After twelve months his r hand became stiff, weak, and uncontrollable, and he noted weakness of the muscles of the shoulder and arm Though conscious of the flickering in the wasted muscles he had at no time had any pain or paræsthesiæ

Examination revealed blood pressure 230/140 mm Hg , heart, lungs, abdomen, and cranial nerves normal , wasting of muscles of shoulder girdle bilaterally, more pronounced on the right , widespread fasciculation in all the affected muscles , both legs spastic , tendon reflexes very brisk in arms and legs , abdominal reflexes absent , plantar reflexes extensor , sensation normal except for diminished vibration sense in the legs

Investigations —The Wassermann reaction was negative blood and C S F The C S F contained 2 cells per c mm. protein 55 mg per 100 ml A blood count and a fracti

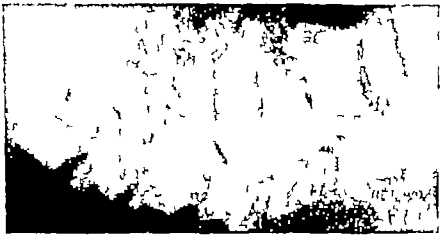

Fig. 1—Case 1: slight diminution of C5–C6 intervertebral disc space, with formation of osteophytes.

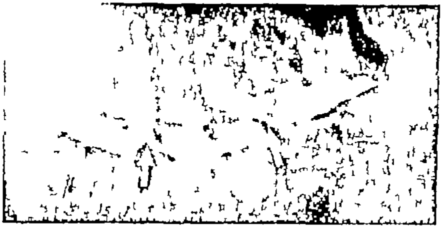

Fig 2—Case 1: interruption of myodil pattern at C3–C4 and C5–C6 intervertebral disc spaces. Patient is prone

test-meal were normal Radiography of the cervical spine showed evidence of osteo arthritic change Cisternal myelography revealed subluxation at C3–C4 with a break in the 'Myodil' column. A more obvious defect appeared at C5–C6.

Diagnosis and treatment—On the radiological evidence the clinical temptation to attach a diagnosis of amyotrophic lateral sclerosis was easily resisted. A leather collar was applied, and there has been some subjective improvement in the patient's condition in the past twelve months although the signs remain unchanged. There is still no pain and still no sensory change

Case 3.—A man, aged 66 was first seen in June 1951 Three years earlier he had experienced progressive weakness of the legs. After eighteen months he noticed in addition that there was an intermittent flickering of the small muscles of the hand followed after an interval of a few months by some wasting Investigation at another hospital at this stage led to the diagnosis of motor neurone disease eminently justifiable on the evidence then available. Shortly before being seen in the neurological clinic, however he had experienced intermittent "deadness" of the legs.

Examination revealed wasting and fasciculation of the transverse head of the left adductor pollicis muscle a spastic paresis of both legs, and a generalised hyper reflexion. The plantar responses were extensor No superficial sensory loss was detected but there was some diminution of vibration sense in the legs. The new complaint of a sense of deadness led to his admission to hospital, and on admission two months after the initial examination he had developed in addition to his motor signs a rather patchy impairment of superficial sensation in the lower limbs His vibration sense was definitely impaired and he made a few mistakes in position sense in the toes.

Investigations—A blood-count was normal The Wassermann reaction was negative in the blood and the C.S.F A fractional test meal was normal The C.S.F contained 1 cell per c.mm., protein 60 mg per 100 ml., and a small amount of globulin. A Lange test was normal Radiography of the cervical spine showed pronounced degeneration of discs and osteo-arthritic lipping Cervical myelography showed indentation of the myodil pattern at C3–C4 C4–C5 C5–C6 and C6–C7 with subluxation at C3–C4

Treatment.—A leather collar was fitted, and with this the patient appeared to improve a little at first In March 1952 however he was readmitted because he said that the numbness in his legs had become more severe and he had begun to have some precipitancy of micturition. Clinical re-examination revealed a very slight increase in his signs, sensory and motor After consultation with Mr Richard Johnson skull traction was applied as a prelude to operation. The patient then developed bilateral femoral thrombosis and subsequent pulmonary infarction, and his subsequent course has been a steady battle against the increasing disability resulting from the enforced immobility His collar was reapplied with great benefit to the fasciculation and wasting in the left hand, which now appears almost normal

Case 4.—A woman, aged 60 was seen on Jan. 30 1953 complaining of weakness of the arms and stiffness of the legs Fourteen months earlier she had fallen in the street but suffered no obvious ill effects. Four months after this however she began to have stiffness in the legs, and within another month she experienced great difficulty in using her hands and arms for such activities as combing her hair and using a knife and fork. The symptoms had progressed steadily until at the time of examination she was bedridden. There had been no pain and no other sensory symptoms. She had been seen at another hospital, where amyotrophic sclerosis had been diagnosed.

Examination showed profound wasting and weakness of the proximal muscles of the arm with slight wasting and weakness of the forearm and hand There was intermittent fascicular twitching of all these muscles The legs were spastic. All the tendon jerks were brisk. The plantar reflexes were extensor Vibration sense was absent in the legs sensation otherwise normal.

Investigations—A blood-count was normal The Wassermann reaction was negative The C.S.F contained 1 cell per c.mm. and protein 50 mg per 100 ml Radiography of the cervical spine showed cervical spondylosis with narrowing of disc spaces C4–C5 C5–C6 and C6–C7 and subluxation at C3–C4 Cervical myelography showed indentations in the myodil column at C4–C5 C5–C6 and C6–C7 interspaces

Cases Simulating Progressive Muscular Atrophy

Case 5—A bus driver, aged 50 was seen on Aug 17 1951 complaining of weakness, wasting and twitching of the muscles of the right arm. Six months earlier he had noted flickering and jumping of the muscles of the right arm and forearm, at times so violent as to awaken his wife at night Two months later he developed difficulty in pulling the steering wheel of his bus round for a right hand turn, and these symptoms steadily progressed. At no time had he experienced any pain or paræsthesiæ

Examination revealed that abnormalities were confined to the right arm and comprised weakness and wasting of all the muscles of the arm forearm and shoulder particularly of the extensors of the wrist. Coarse fasciculation was noted in all the affected muscles, but mostly in biceps and in the extensors of the wrist The tendon reflexes were a little brisker in the right arm. There was no sensory loss

Investigations—A full blood-count was normal. The C.S.F was under a pressure of 120 mm. H_2O dynamics normal and contained 1 lymphocyte per c.mm., protein 35 mg per 100 ml and no increase of globulin A Lange test was normal The Wassermann reaction was negative in blood and C.S.F Radiography of the cervical spine showed disc degeneration with osteo-arthritis in all the lower cervical segments, as was also shown by cervical myelography (fig 3) there being a definite break in the myodil at C4–C5 disc space

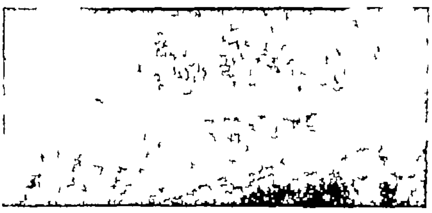

Fig 3—Case 5: abnormality of C4–C5 C5–C6 and C6–C7 intervertebral disc spaces. In myodil pattern there is only a trickle of myodil lying in the left lateral gutter compared with good filling above and below lesion. Patient is prone

and poor filling from C4–C5 to C6–C7 due to lifting of the dura by osteophytes.

Treatment.—A leather collar was fitted to this patient on March 7, 1952, and after he had worn it for only two weeks the coarse fasciculation of the arm had subsided greatly. At the end of two months there was no involuntary movement at all. The right forearm was still thin, but no fasciculation could be seen. The wearing of the collar was reduced to half days. After four months he was driving his bus normally, wearing his collar only when not on duty. When last seen on March 27, 1953, he was perfectly normal, with full strength in all muscles, and had been without the collar for three months.

This patient is of special interest for three reasons: (1) the purity of the motor signs and symptoms; (2) the extreme changes in the cervical spine accompanied by a strictly circumscribed diminution of function, in contrast to the findings in case 1, who, with scanty neurological findings, was much more disabled physically; and (3) the great benefit which can result from conservative treatment of this type of case.

Case 6.—A man, aged 56, was seen on Oct. 9, 1952, with three years' history of progressive weakness and wasting of the left hand and arm. Six months before being seen he developed some wasting of the small muscles of the right hand and had himself noticed a little twitching of the "muscles near the thumb." At no time did he experience pain or paræsthesiæ, though he had noticed some aching of the muscles of his neck if he remained in one position for any length of time.

Examination revealed that abnormalities were confined to the motor system and to the upper limbs. There was pronounced wasting of the small muscles of the left hand. The muscles of the left forearm seemed a little thinner than those of the right. On the right side there was some wasting of the interossei and there was fasciculation in the transverse head of the adductor pollicis. All the reflexes were brisk. There was no sensory loss, and the plantar responses were flexor.

Investigations.—A blood count was normal. The Wassermann reaction was negative in blood and C.S.F. The C.S.F. was under a pressure of 40 mm. H_2O, dynamics normal, and contained 1 lymphocyte per c.mm., protein 35 mg. per 100 ml., and no increase of globulin. A Lange test was normal. Radiography of the cervical spine showed osteo-arthritis with disc degeneration in the lower cervical segments. Cisternal myelography revealed a frank protrusion into the myodil column at the C6–C7 disc space consisting mainly of posterior osteophytes (fig. 4).

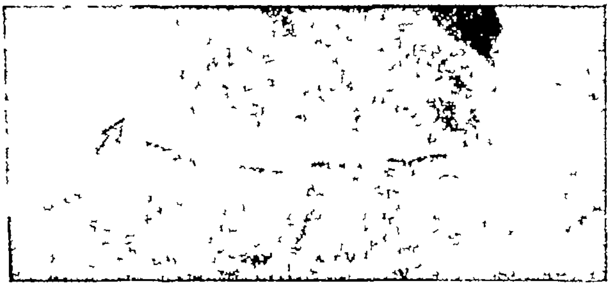

Fig. 4.—Case 6: large dent in myodil pattern at level of diseased C6–C7 intervertebral disc.

Treatment.—A leather collar was fitted to this patient on Jan. 5, 1953, and when seen on April 14 he showed great improvement. An enthusiastic pianist, he had suffered considerable disability during the development of his muscular weakness, but after the application of the collar he rapidly improved. The degree of muscle wasting was less, the power in the hand increased, and the fasciculation of the adductor pollicis had cleared. There was still some weakness of the interossei, but power was still increasing.

Case 7.—A woman, aged 45, was seen on Jan. 30, 1953, complaining of weakness of the hands. Three years previously she had experienced difficulty in extending her right index finger. After two years the ulnar three fingers of the left hand developed similar trouble, while the right hand also became increasingly clumsy.

Examination revealed wasting and weakness of both forearms, particularly of the extensor groups. There was also some weakness of the interossei, and fine movements could not be performed well. The left arm jerks were diminished and the left plantar reflex was doubtful. Sensation was normal in all modalities. Examination at another clinic led to a diagnosis of progressive muscular atrophy.

Investigations.—Electromyography revealed fibrillation potentials in the extensors of the wrists and fingers, and in the left first dorsal interosseous muscle. Radiography of the cervical region showed definite diminution of C5–C6 and C6–C7 disc spaces, with associated posterior osteophytes, and myelography confirmed these abnormalities.

Case 8.—A man, aged 57, seen on March 28, 1953, stated that twelve months previously he had first experienced difficulty in holding a golf club with his left hand. He had no pain and no sensory disturbance. After six months he noted wasting of the small muscles of the left hand, particularly in the first interosseous space. The condition had progressed slowly but steadily, and he began to notice flickering in the medial muscles of the forearm, as well as in the hand. Progressive muscular atrophy had been diagnosed before his arrival at the neurological department. His previous medical history was irrelevant, and there was no history of injury.

Examination revealed that the abnormalities were confined to the muscles of the left hand. There was loss of muscle bulk in the transverse head of the left adductor pollicis, with guttering of the hand. The hypothenar and thenar eminences were reduced on this side, and there was definite weakness of the wasted muscles. Fasciculation was seen in the transverse head of the adductor pollicis. Sensation was normal. The reflexes were brisk and equal.

Radiography of the cervical spine showed considerable disc degeneration and osteophytosis at C5–C6 and C6–C7.

Discussion

The questions raised by these cases may be grouped under diagnosis and management.

Diagnosis

The diagnostic significance is obvious, and is emphasised particularly by case 1, in whom a very reasonable diagnosis of motor-neurone disease was made twelve years earlier. The bad prognosis of motor-neurone disease is such as to discourage this diagnosis, and the knowledge that cervical spondylosis may simulate motor-neurone disease so closely leads to the careful investigation of this diagnostic possibility. Of our 8 patients 6 were male, and these, though all aged more than 50, still retained a useful position in the community. Case 1 indicates the length and type of course which may be expected in the cervical spondylotic, even without treatment—a point of considerable importance in advising patients and their families.

Management

The best course of action is not yet clearly defined. Indeed, one is tempted to suggest that no single line of therapy will ever prove to be correct for all the cases.

It seems reasonable to suppose a priori that operation in spondylosis with diffuse affection of the various intervertebral joints is unlikely to produce a very satisfactory result unless there is a very large single filling defect in the myodil pattern on myelography, and even in such cases simple excision may not yield any great benefit. The intention in case 3 (in coöperation with the department of neurosurgery) was to apply traction and then to excise the supposed projecting disc and osteophytes, but the period of immobilisation carried with it its own unfortunate sequelæ. Even in this patient, however, considerable improvement has taken place in the weak, wasted, and fibrillating left hand as a result of the application of a leather collar.

The next most active line of therapy is to apply skull traction for three or four weeks, and then to put on a Minerva plaster for from three to six months. This has certainly produced satisfactory improvement in some cases of cervical spondylosis but was not used in the present series.

The third main course open (apart from no treatment at all) is the application of a collar with breast and back plate (made of either leather or moulded plastic) This method proved very successful in cases 4 and 6 and partially so in case 3 and has been used with similar success in some of our other cases without pyramidal signs and particularly where pain was severe Bony fixation with grafts into the cervical spine has been suggested as a means of producing more permanent splinting of the affected region

Clinical Pictures

Numerous theories have been advanced to explain the diverse clinical pictures produced by these osteochondral abnormalities The concept of direct pressure of the projections upon the cord, the rootlets within the theca or the combined roots at their point of emergence through the intervertebral foramen has the appeal of simplicity and has been favoured by Spurling (1944) Spillane and Lloyd (1952), and Brain et al (1952) That this is not entirely true is suggested by the response of cases to restriction of movement of the cervical spine This improvement appears to support the alternative suggestions of direct rubbing of the cord and roots on the osteochondromatous projection (Bedford et al 1952) or else of intermittent interference with the blood supply —again by relative movements of the spine and cord— from the anterior spinal artery and its branches. In further support of this is Allen's (1952) observation on blanching of the cervical cord during operation when the neck was flexed It is quite possible that both these mechanisms are at work but in either case temporary fixation would produce improvement both of upper and lower motor neurone symptoms Our present advice to these patients is that they should wear their collars *continuously for the first three months, then wear them* only at work or at times of fairly active movement as in recreation, for a further three months We suggest that after that time the collar may be left off to await developments. Only time will show the long term value of this course

Summary

Of 8 cases of cervical spondylosis 4 displayed the clinical picture of amyotrophic lateral sclerosis and 4 that of progressive muscular atrophy

In treatment the application of a leather collar has given good results, particularly when a lower motor neurone affection is predominant

It is a pleasure to acknowledge the help received from Dr F R. Ferguson, under whose care the patients were. The radiological findings are reproduced by courtesy of Dr R G Reid and Dr C P Moxon, of the department of neuroradiology and with the help of Dr R G Ollerenshaw of the department of medical illustration

If a city is miraculously efficient, crammed with goods bristling with services, glittering with all the latest ingenuities, but is also filled with people who are worrying themselves sick or becoming ugly minded and cruel or turning into dim robots, then that city is a flop If the people in the neighbouring country are comparatively poor have few possessions, no gadgets, no great organisations, but contrive to live zestfully laugh and love still enjoy poetry and music and talk then that country has succeeded. —J B PRIESTLEY *New Statesman and Nation* Sept 5 1953, p 251

MALARIA CONTROL IN BORNEO

JOHN McARTHUR
M.P C.S

LATE DIRECTOR OF MALARIA RESEARCH IN NORTH BORNEO SARAWAK, AND BRUNEI

JUST after the war I reported that *Anopheles maculatus* the chief vector of malaria in Malaya, was of no importance as a vector in Borneo whereas *A balabacensis* (then known as *A leucosphyrus*[*]) generally regarded as harmless in other countries was the chief and generally the sole vector throughout the greater part of Borneo (McArthur 1946)

It had been found that *A balabacensis* bred only under jungle shade and that clearance of shade and admission of sunlight led to immediate disappearance of this mosquito It was natural therefore, to suppose that clearance of jungle over breeding places of *A balabacensis* would eradicate not only this insect but also the malaria which it carried. There was a good deal of indirect evidence in support of this supposition and in view of its practical importance an experiment had been begun before the war in Tambunan, North Borneo This however had been interrupted by the Japanese occupation

PRESENT INVESTIGATION

In 1949 this experiment was again established In the selected area of about ten square miles, which was occupied by five villages the proportion of the population having enlarged spleens had averaged just over 80% in the previous thirteen years In this area the breeding-sites of *A balabacensis* were carefully defined and they were then cleared to admit sunlight by a gang of about 50 coolies working for about three months *Finally, the incidence of malaria in the area was* investigated in each of the next three years

This valley was selected partly because the prevalence of malaria in it had remained practically the same for many years and partly because it was one of the most difficult situations to deal with so that the experiment might be completely convincing

RESULTS

Breeding —The breeding of *A balabacensis* had been widespread in this valley during every examination for many years. Shortly after the clearing operations in 1949 the breeding of this mosquito fell to about 5% of its previous level, and this degree of control appears to have continued over the whole three years of the experiment without significant further work.

Enlarged Spleen —The spleen rate which had remained constant for many years in this valley was 86% just before the clearing A year after the clearing it had fallen for the first time on record to 56% and in the next two years it fell to 53% and 45% successively This reduction may reasonably be attributed to the clearing and to the control of *A balabacensis* breeding

Transmission of Malaria —Some transmission of malaria remained however as was shown by parasites in the blood of young babies This was probably due to the infiltration of infected *A balabacensis* through the jungle from surrounding highly malarious villages It is therefore extremely desirable that further work should be done over a wider area to eliminate such infiltration

Comparison Area —A very interesting finding was made in a neighbouring valley which had been selected as a comparison area In this valley the spleen rates had remained steady at 100% at every examination in thirteen years but it suddenly fell to 75% during the last survey in 1952 and for the first time on record children were then found without evidence of malaria This seemed at first to render the observations in the experimental area invalid , but an examination of the comparison area discovered the probable reason

---

[*] Recent research has shown that the vector of malaria in Borneo is more correctly called *Anopheles leucosphyrus* var *balabacensis* or *A balabacensis* and this name will henceforth be used (Colless 1950)

For many years previously conditions had remained exactly the same under an elderly village headman In 1951, however, this old man died and was succeeded by a new and younger headman, who cleaned up his village, distributed drugs to the children, and applied anti mosquito measures by drainage and clearance Thus, far from invalidating the findings in the experimental area, this village proved the ability of the people to tackle malaria on their own initiative

The clearing in the experimental area lasted much longer than was at first expected, and such clearing can be maintained permanently if the people cultivate, or graze their cattle in, the moist fertile areas thus exposed Newer methods of clearing by spraying with selective herbicides—one spraying of which is claimed to be effective for five years—may prove an economical means of malaria control which is worthy of further study

CONCLUSION

This experiment, therefore, has given to Borneo a proved method of malaria eradication which is simple yet effective, economical, and permanent , which can be put into effect by the villagers , and which at the same time encourages the agricultural and economic development of the country

It is hoped that this method may be of value in all those areas where *A balabacensis* is the vector—over the hilly jungle covered country which extends from Assam in the east as far as Celebes in the west

SUMMARY

Jungle clearance with the admission of sunlight to breeding-places of *A balabacensis* led to a 95% reduction of breeding of this mosquito, and a significant fall in the incidence of enlarged spleens in an area of hyperendemic malaria

The importance of extending the area is emphasised, to eliminate the possible infiltration of infected mosquitoes from other areas

This method of malaria control is effective, economical, and permanent , can be put into effect by the inhabitants , and contributes to the health and wealth of the land

A FOREIGN BODY IN THE ILEUM

C M. Ottley
M.A., B.M. Oxfd, F.R C S
SURGEON, NEW SUSSEX HOSPITAL FOR WOMEN, BRIGHTON

It is difficult to understand how a metal object almost as large as a halfpenny can be swallowed unwittingly by a person apparently sane and sober , but, as the following report shows, the thing can be done

A woman, aged 61, was sent to the outpatient clinic by Dr L Garrett with a diagnosis of subacute intestinal obstruction, probably caused by adhesions following a total hysterectomy for fibroids twelve years previously The patient stated that two weeks earlier she had been suddenly seized with severe abdominal pain and had vomited once She had had a similar attack of pain a year before, but it lasted only a few hours and she did not send for the doctor On the present occasion the pain continued to recur in colicky fashion and the doctor was summoned The patient stoutly refused to allow him to arrange immediate admission to hospital and insisted on being treated at home There was no more vomiting and the bowels acted daily, but attacks of colic continued to occur, and she finally consented to go to hospital as an outpatient

Examination disclosed only one abnormality an area, no larger than a sixpence, just to the right of the right median subumbilical scar left by the hysterectomy, where extreme tenderness was felt on pressure

Laparotomy was done two days later No adhesions were found at the site of the hysterectomy, but a loop of the lower ileum, about a foot above the ileocæcal valve, was stuck to the anterior abdominal wall at the point where tenderness had been noticed on examination When freed, this loop was felt to contain a mass which, through the intestinal wall, [illegible] an ulcer crater with very hard floor and heaped up edges Several enlarged but soft lymph glands were felt in the adjacent mesentery Search through the abdominal cavity revealed no other lesion and, supposing that I was dealing with that rarity a primary malignant growth of the small intestine, I excised about 10 inches of the loop with its mesentery and did an end to end anastomosis When, however, at the end of the operation the loop was laid open, it was found that the " ulcer crater " was formed by a saucer shaped piece of fine mesh wire gauze 24 mm in diameter, probably part of a tea strainer This lay in the long axis of the bowel and had produced ulceration at two points on the mesenteric and antimesenteric borders of the much thickened wall of the bowel On the antimesenteric border the ulceration had involved the muscular coats and caused adhesion of the loop to the abdominal wall

The patient made an uneventful recovery She learned with surprise of the foreign body and was quite unable to remember any occasion when she might have swallowed it, which she probably did shortly before the attack of pain a year previously

---

Preliminary Communication

DIMINISHED URINARY EXCRETION OF CITRATE DURING DEFICIENCIES OF POTASSIUM IN MAN

The method of Hargreaves et al[1] has been used to measure the rate of excretion of citrate in the urine and the concentration of citrate in peripheral venous plasma during states of potassium deficiency Most of the observations were made during the course of the deficiencies of potassium induced in two normal men (A and B) by the ingestion of a cation exchange resin and of a diet containing little potassium (cf Fourman and Ainley-Walker[2])

Total deficits of 300 and 450 m eq of potassium were achieved in the two men, who experienced general malaise, loss of appetite, and constipation but were not severely ill After the administration of the resin had been stopped, small amounts of potassium were retained from the diet, but the deficits were not completely made good until extra potassium had been given There was a moderate extracellular acidosis while the resin was being administered, but this was rapidly corrected afterwards by the absorption of sodium, some of which entered the cells

The urinary excretion of citrate was also measured in a woman, aged 44, with renal acidosis who was losing excessive amounts of potassium in the urine

RESULTS

The accompanying table shows that during the control period A excreted about 160 mg , and B about 380 mg of citrate a day They excreted only 38–70 mg a day when they were deficient in potassium, and the amounts were independent of the acid-base balance in the plasma and of the urinary pH The excretion of citrate remained low when 96 m eq of potassium was administered daily as the citrate and did not return to its control value until the deficiency of potassium had been completely made good The low urinary excretion of citrate was not associated with a demonstrable fall in the plasma citrate level and therefore was presumably renal in origin.

---

[1] Hargreaves, C A Abrahams M. D , Vickery, H B *Analyt Chem* 1951 23, 467

[2] Fourman P , Ainley-Walker, K. M S *Lancet* 1952, ii, 368

The woman with renal acidosis had a plasma bicarbonate level of 15 m eq per litre, and her urinary pH was 7 3–8 0 She excreted 4–74 mg of citrate daily and did not excrete more when she had been given 15 g of KCl daily by mouth for some time. It is not yet known whether her deficiency of potassium can be corrected in this way

URINARY EXCRETION OF CITRATE

Period	Day of expt.	Total K deficit (m.eq)	Plasma CO_2 (m.eq per litre)	Urine pH	Urinary citrate (mg per 24 hr)
Subject A (age 26 weight 56 kg)					
Control	0–4	0	27	6 7	108
	4–8	0	28	6·5	118
With resin	8–12	280	17	5 7	38
	12–16	330	23	6 1	72
After resin	16–18	270	29	6 1	45
	18–20	200		6 4	42
K citrate added to diet	20–21	80		6 7	64
	21–23	0	31	7 4	116
Subject B (age 29 weight 7 kg)					
Control	1	0	28	5 9	410
	5	0	27	6·0	353
After resin	14	390		6·0	57
	15	360	22	6 2	69
	16	330		6 4	66
	17	300		6·6	105
	18	270	30	6 7	123
K citrate added to diet	19	145		6·0	66
	20	15		7 3	275
	21	0	27	7 4	300

DISCUSSION

The quantity of citrate normally excreted is 0 20–1 0 g It varies inversely with the concentration of hydrogen ions in the urine, but citrate is so completely metabolised that the urinary output bears little relation to the dietary intake[3] Our results have disclosed that during a potassium deficiency the rate of excretion of citrate may become low and remain so even when the urine has been made alkaline by the ingestion of citrate. The precise functions of potassium in cells are uncertain, but any connection between the most abundant intracellular cation and an intermediary in the tricarboxylic cycle through which most of the aerobic metabolism of the body is mediated is of interest It may be noted that the metabolism of glucose becomes depressed by a deficiency of potassium[4] These preliminary results suggest that further investigations of the metabolism of citrate during potassium deficiency are desirable

SUMMARY

The urinary excretion of citrate was measured in two normal men before during and after an experimental deficiency of potassium

The excretion of citrate was diminished while the men lacked potassium

It was also diminished in a patient with renal acidosis and potassium deficiency

Clinical Tropica

A. R D ADAM
department; B
professor of tropica
Medicine Oxford
1953 Pp 508 40s

A NEW book on tropical
as coherently constructed
authors have confined thems
physician and the pathologist
see them in hospital for there ... ore
of the atmosphere of the equipp ... of the
dispensary or field unit of the trop ... iberately
avoid discussion of the parasites an ... —details of
which are readily available in oth ... oks—and say little about prevention and control These are self imposed restrictions; and the book within its chosen scope is admirable The writing is clear terse and intentionally dogmatic as students like it. Subjects are taken alphabetically—ainhum first and yellow fever last—with the odd result that in the middle between melioidosis and mycetoma pedis, there is a chapter on miscellaneous worm infestations.' Blackwater fever under this arrangement, is a far cry from malaria; but this does not matter since the ætiology is made perfectly clear The authors have included a surprisingly large amount of modern and important information—though the account of Q fever could be expanded This first-class book can be strongly recommended to clinicians

The Liverpool school has already produced a textbook of parasitology, there now remains the need for one on tropical hygiene, in which the diseases of people living in the tropics can be studied in relation to their background

The Neuron

Organiser: M. DEMEREC Symposia on Quantitative Biology Cold Spring Harbor Vol 17 1952 Pp 323

THE display of experimental ingenuity and inductive virtuosity contained in many of the papers included in this volume is impressive. A glittering array of neurophysiological authorities—Lorente de No Bodian, Bronk, and, from the non American world, Eccles Monnier, and Hodgkin—met last year to share their knowledge and stimulate their ideas on the neurone by discussing the properties of nerve axons the peripheral origins of nervous activity and the neurone soma and its electrophysiological properties as well as to review cortical, spinal, sympathetic and junctional nervous activities These discussions were for the most part rather speculative and the speakers are at some pains to confess the possible defects of their conjectures.

There is a neat contribution by C R Skoglund on the chemical factors modifying transmission through the cat s spinal cord. Few will fail to be impressed by the lucid realism of David Bodian s introductory survey of neurones the directness of A. L. Hodgkin and A. F Huxley in their discussion of sodium and potassium ions during nervous activity and the uncontested ingenuity of J C. Eccles in evolving a neuronal model which appears to explain much of the behaviour of motor neurones in experimental investigations.

All will come to understand the neurophysiologist s debt to that benign providence which placed in the waters of the earth the squid with its giant nerve-fibres.

Gynecological and Obstetrical Pathology

PETER A. HERBUT M.D professor of pathology, Jefferson Medical College Philadelphia. London: Henry Kimpton. 1953. Pp. 683 93s 6d

THIS is a carefully compiled book. For each subject in turn Dr Herbut has studied several recent reviews and fused them to form a short compendium of modern knowledge

This method is very successful with topics of which he obviously has extensive personal experience for this enables him to select his reviews well, and assess the evidence critically On topics with which he is not so familiar however he lacks the confidence to differentiate the traditional from the true and gives lists which could have been assembled almost as

Most of the standard gynæco
on record children were th with, and, in addition, information
of malaria This seems of rather esoteric conditions such as
tions in the experi the cervix, blastomycosis of the uterus,
tion of the coma of the fallopian tubes The sections on
reason uloma and on granuloma inguinale are well done,
For ere is a full and useful chapter on the placenta The
chapter, on "The Mother," not by Dr Herbut, is below the level of the rest of the book

In this country there is a tradition that pathology is to be studied only through the mortuary, the museum, and the microscope This book shares the broad outlook of several other American textbooks, where pathology is interpreted as the scientific study of disease in all its aspects—disturbances of function as well as of structure, reasons for characteristic signs and symptoms, specific lines of treatment, and prognosis

Clinical Electrocardiography

Textbook for Practitioners and Students MAX HOLZMANN, Zurich, translated by DOUGLAS ROBERTSON, D M, M R C P London Staples Press 1952 Pp 647 105*s*

Prof Holzmann's book is not for the beginner, but for the advanced student, research-worker, and experienced cardiologist

The electrophysical basis of the electrocardiogram obtained by limb and chest leads, and the methods and theory of vectorcardiograms, are thoroughly considered Œsophageal and intracardiac leads are also dealt with, but briefly The important and sometimes overlooked effects of posture, exercise, and other physiological stresses on the picture are well set out Passing to the abnormal, the auriculogram and axis deviation are discussed in unusual detail The section on the electrocardiogram in the various grades of myocardial ischæmia is adequate though not so full, considering its importance, as some other sections, and perhaps there is too much insistence on exercise tests There are a few printer's errors, and the style often recalls that this is a translation

The book throughout is hampered by a Germanic thoroughness which makes it heavy going, but it is a work of the first importance

The Sensory Order

An Inquiry into the Foundations of Theoretical Psychology F A HAYEK, professor of social and moral science, University of Chicago London Routledge & Kegan Paul 1952 Pp 209 18*s*

FEW psychologists would have the courage to venture as deeply into economics as Professor Hayek here does into psychological territory In the preface he explains that as a young man hesitating between economics and psychology, he conceived some basic ideas about mind as a particular order of symbolic events, these he has developed into the present work, based not upon experiment and direct observation but on reflection, reading, and the experience of a student of social theory The outcome, necessarily speculative and philosophical, takes less account of recent developments in neurophysiology than the thesis requires, concerned as it is with the whole of the neural events which accompany sensory experience It is nevertheless a notable contribution to the theory of perception, and it adds a footnote to the mind-body problem while denying "any ultimate dualism of the process governing the realms of mind and that of the physical world respectively," Professor Hayek recognises that "for practical purposes we shall always have to adopt a dualistic view"—a seeming inconsistency which he defends in his final chapter on "Philosophical Consequences"

Storming the Citadel

The Rise of the Woman Doctor E MOBERLY BELL London Constable 1953 Pp 200 18*s*

MISS Moberly Bell has written a very entertaining and at times exciting account of the rise of the woman doctor, and the foundation and development of the Royal Free Hospital School of Medicine In the main it is concerned with the early struggles, disappointments, and final triumphs of Elizabeth Blackwell Elizabeth Garrett, and Sophia Jex-Blake The debt of all medical women to these three, and in particular to the last, can hardly be overestimated She alone had the imagination to see the immense value of a school of medicine run for and by women Yet when the school had begun it was realised that she was temperamentally unsuitable for the post of secretary which she longed to hold Sophia never showed more finely the essential generosity of her spirit than in the way she took this bitter disappointment she left London and returned to Edinburgh, the scene of her earlier struggles But she would have been more than human had she been equally generous when Elizabeth Garrett Anderson was about to be appointed dean, for Elizabeth had opposed the foundation of the school Moreover she believed—unjustly—that it was Elizabeth who had prevented her from becoming secretary She returned to London to record her dissentient vote, but Elizabeth was elected, and that was the end of any pleasure Sophia could take in the London School of Medicine for Women

The male reader cannot but feel ashamed at the outrageous way his forbears treated these aspiring women, but that should not lessen his interest and delight in an unusually readable book Medical women will read it with pride, and with gratitude to the small band of very courageous women Both will agree that it is well that such energy is no longer dissipated in a fruitless struggle between the sexes

---

Functional Disorders of the Foot *Diagnosis and Treatment* (3rd ed Philadelphia and London J B Lippincott 1953 Pp 345 52*s*) —The appearance of a third edition of this little book by Prof Frank D Dickson and Dr Rex L Diveley is evidence of a call for it, and the personal popularity and high reputation of its two authors on this side of the Atlantic will certainly enhance its appeal in this country Some new material on architectural defects of the bones of the foot as a cause of foot imbalance and on other subjects has been added, and the chapter on rigid flat-foot has been rewritten to embody the fine work of Harris and Beath On the whole it is a valuable book, particularly in the emphasis laid on acquiring stability and balance in the foot of the child and adolescent Some of our own shoemakers might take to heart the comments made on the proper design of footwear, even though the authors apparently accept as inevitable that correct principles must give way to "style" when years of indiscretion are reached This book has the weakness of being highly repetitive, not always for the sake of accentuating the point at issue Some of the statements (e g, that "calcium and phosphorus deficiency are unquestionably the underlying cause in most cases of knock knee and bow legs") are questionable, and excision of os calcis spurs has long been abandoned in this country as giving no benefit Not all the illustrations are of high quality Nevertheless, the emphasis of the book is all on the clinical and functional side, and it has already succeeded in its main design "to stimulate the interest of the medical profession in disorders of the feet"

Trusts and Foundations (Cambridge Bowes & Bowes, 1953 Pp 194 42*s*) —Compiled by Mr Guy Keeling and edited by Mr Thomas Landan, this is a pioneer attempt to provide a guide to grant making bodies It is not a comprehensive survey by any means as Mr Keeling says in his preface, only the Government would be in a position to make that There are 110,000 known trusts and foundations in England and Wales alone, and the actual figure is thought to be even higher This guide only deals with some 1000 scattered through Great Britain and the Commonwealth Lord Nathan, in a foreword, mentions the inconvenience caused to would be beneficiaries by the lack of full and precise information about such trusts, and describes the book as an illuminating cross section It gives details of the purpose and conditions of all the trusts listed, and carries a classified index, an appendix on Government grants to voluntary agencies, a bibliography of sources of information, and several blank pages for notes The publishers intend to issue further editions incorporating additional information This looks like the beginnings of a very useful service indeed

Symposium on Fatigue (London H K Lewis & Co 1953 Pp 196 24*s*) —In March of last year the Ergonomics Research Society held a symposium on Fatigue, of which we published a report (*Lancet*, 1952, i, 868) Many of the papers read then have now been brought together in a book, well printed and illustrated, with a foreword by Mr W F Floyd, PH D, and the Rev A T Welford, who have edited it All those working on this perplexing subject will be glad that this material has been published

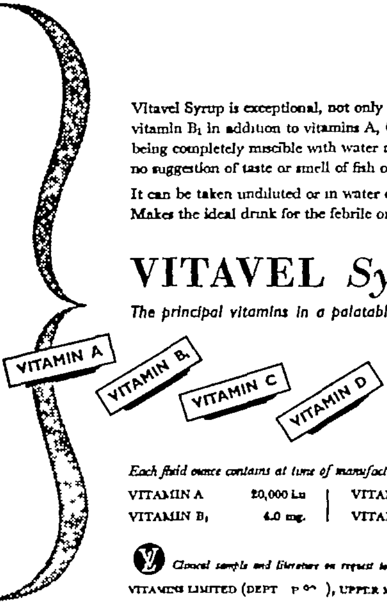
PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD DAGENHAM

A vitamin prescription suitable

for patients of all ages



Vitavel Syrup is exceptional, not only in containing vitamin B_1 in addition to vitamins A, C and D but in being completely miscible with water and having no suggestion of taste or smell of fish oil.

It can be taken undiluted or in water or soda water Makes the ideal drink for the febrile or debilitated patient.

VITAVEL *Syrup*

The principal vitamins in a palatable orange base

Available in bottles of
6 fl. oz. 3/9
40 fl. oz. 21/- less usual professional discount.

Each fluid ounce contains at time of manufacture

VITAMIN A	20,000 I.u	VITAMIN C	80 mg
VITAMIN B_1	4.0 mg.	VITAMIN D	3,000 I u

Clinical sample and literature on request to

VITAMINS LIMITED (DEPT P 9^), UPPER MALL, LONDON W.6

The Relentless Mirror

Time is a gentle deity but how cruel it can be to woman in her middle years

To the woman at the menopause, a glance in the mirror reveals so much more than a reflection of her face Apprehension, flushing, irritability and depression confront her and the calm philosophy that has stood her in good stead through the years no longer mellows her reflection

Euvalerol M, the ideal sedative in menopausal conditions, alleviates nervous phenomena and vasomotor disturbances and restores the emotional outlook

Euvalerol M contains a preparation obtained from valerian root from which the unpleasant odour, characteristic of valerian, is eliminated To each fluid drachm (4 c c) of this odourless preparation of valerian are added ¼-grain (16 mg) of phenobarbitone and 0 1 mg of stilboestrol

EUVALEROL M

In bottles of 4 and 8 fluid ounces

Literature on application.

General Practice

THE *British Medical Journal* this week publishes a mass of new material on the state of general practice in this country, together with an analysis of the opinions of practitioners on the work they are doing. A committee of the British Medical Association, with Dr C W WALKER as its chairman, presents recommendations which are chiefly aimed at bringing practitioners into closer relation with the hospital and public-health services and which are important to all sections of our profession because they are a major attempt to counter the tendency to its fragmentation.

The journal opens with a report by Dr STEPHEN HADFIELD, an assistant secretary of the B.M.A., on the observations he made personally on 188 practices in each of which he spent the best part of a normal day between February, 1951 and March, 1952. Unlike Dr J S COLLINGS, whose disturbing "reconnaissance had lately been described in our columns,[1] Dr HADFIELD was in a position to take a cross section of the entire body of general practice in Great Britain instead of selecting a number of more or less representative types of practice he was able to compile a more comprehensive sample—the initial list being formed by taking every 64th name in the list of practitioners in each region. Necessarily, as in the Collings survey, his approach was critical 'in the hope that the discovery and assessment of shortcomings faults, and difficulties might lead to action which would eliminate them' but his forbearing judgments are less emphatic and he is evidently not concerned to convey the same urgent impression of widespread deterioration in practice for lack of proper facilities to do good work. But what he saw was not perhaps very different from what COLLINGS saw. At the time of his survey he says, 49% of practitioners had premises adequate for maintaining a high clinical standard and 17% had premises which were more than adequate but in 24% something essential was missing and 10% were unsuitable. (He rightly adds that "while present housing conditions prevail a knowledge of the facts is necessary before premises are criticized.) His comparative satisfaction with equipment ("on the whole the standard is quite adequate as to essentials") is somewhat offset by his remark that many practitioners have electric sterilizers and those that have not usually have available some method of sterilizing instruments'. Facilities for examination, such as an examination couch, were missing from 11 surgeries, and Dr HADFIELD was surprised at the prevalence of the method of examining the abdomen through the clothes and with the patient standing. A statement that at least 60% gave all their patients what examination was necessary does not again, entirely restore confidence shaken by the previous observation that 93% *of the doctors he watched at work made* 'some sort of examination in some cases". A quarter of them he thought, seemed to pay rather scant attention to record keeping, and only about half had some form of secretarial or clerical help suited to their needs. We bring out these less favourable findings from the survey because we think it should be fully understood that the conditions under which practitioners are obliged, or have accustomed themselves to practise are still quite commonly defective in ways that can and must be put right. Dr HADFIELD found that in a substantial proportion of practices lack of time had reduced the range of service the doctors could give their patients, but he felt that the large majority would not allow their work to be so hurried as to interfere with its quality. Though with more work there was less time for friendly converse only 6% of the practitioners visited regarded their relationship with their patient as a purely matter-of fact or business-like one nearly all were ready to give helpful advice on health and preventive medicine when asked by the patient and about nine out of ten regarded the giving of non medical advice as a part of their calling. In view of contrary statements it is good to note that most of the doctors visited were anxious to keep in close touch with patients receiving hospital treatment that the majority showed an interest in the family and occupational background of the patient and that 96% believed that if possible the doctor should really be a family doctor, attending the whole family. It is encouraging, too to read that, even in those financially darker days of 1951–52 a large body of the profession could be described as receptive towards the N H.S ready to like it more and more and determined that a good service shall evolve with full benefit for the patient and contentment for the general practitioner'.

Dr HADFIELD had a series of questions which he regularly put to the doctors he visited, and his report summarises the replies. To supplement this personal interrogation the General Practice Review Committee on July 12, 1951 posted similar *questions* to the rest of the general practitioners in the country whose voices, as it said, might not otherwise be heard. To make the questionary less formidable and promote fuller answers, it divided the practitioners into groups of 450–500, each of which got only two questions, and in the end it obtained facts and comments from 12 657 doctors (72% of the possible response). Belonging as they do to the pre-Danckwerts period some of these facts and comments are out of date, but others remain at least as significant as they were two years ago. What is chiefly evident from them is the impossibility of reviewing the activities of general practitioners usefully without also discussing the habits of a great many other people, such as consultants housemen ward sisters administrators midwives health visitors medical officers of health the writers of medical articles in the popular press —and of course patients and their relatives. In a service that claims as one of its biggest achievements so far the wider distribution and greater accessibility of specialists it is discouraging to read so much evidence of the frequent failure of consultants —especially among the younger generation—to give

---

1 *Lancet* 1950 i, 555 547

the practitioner the help he really needs It is not always easy to remember, or even believe, that what is in itself a highly efficient and skilful specialist unit or service may fall far short of success when looked on as part of comprehensive medical care, and in considering how far he is making the practitioner's work easier, or more difficult, every consultant will do well to ponder the many passages in this report that express disappointment with hospitals Here are two—one tolerant and one severe

> "The difference is subtle and hard to define I am still on the very best of terms with our local consultants, as before, but somehow there is a difference In the old days one used to ring them up constantly and discuss cases and people Now one feels they are no longer dependent on us, and they seem to be so much taken up with clinics here, there, and everywhere, and somehow one doesn't like to bother them"
>
> "Many consultants now exercise much less care or even courtesy in reference to the practitioner The patient's confidence in his own doctor is of much more value to him in the long run than the occasional 'cleverness' of a consultant This confidence is in the best interest of the patient and should be fostered and not destroyed"

Confidence is destroyed in another way by the hospital which does not get in touch with the practitioner at once when his patient is discharged or even when his patient dies Here as elsewhere it is failure of contact that is the trouble, and the same failure is seen all too often and all too plainly between practitioners and public health doctors ("having been in practice here for the last 40 years, I have never even met my three district M O H S") "My foremost impression," Dr HADFIELD says, "is that of lack of unity in the N H S and lack of unity in the medical profession The human gaps must be closed The general practitioner, the consultant, and the public health medical officer need to get to know each other and then to learn to work in concert"

In its recommendations the committee lays less stress than some of us on the development of group practice, though it welcomes the tendency of practitioners to associate for their work Its main desire is to bring general practice into closer relation with public health on the one hand and hospitals on the other, composing the differences and closing the gaps between the three branches of the N H S, for "medicine must be practised as a unity" The practitioner can and should work more happily and advantageously than he usually does with the M.O H, the clinic doctor, the midwife, the health visitor, and the district nurse At the hospital he should have direct access to pathological and radiological departments, he should be able to perform minor surgery, he should have beds wherein to conduct confinements, and others where he can treat patients for "general-practitioner" conditions, he should hold clinical assistantships, and he should be a welcome visitor in the wards The patient whom he refers to a particular consultant should not be seen by an assistant unless the consultant expressly delegates this duty, and in emergency the hospital to which he normally sends his cases should share with him the onus of finding a bed for his patient With all this we strongly concur But in the further suggestion made to the committee, "that, just as every patient has his own doctor, so every practitioner sh have his own hospital" we see need for caution The risk is that, in seeking to overcome the isolation of general practice we may end b turning the practitioner into a peripheral and subordinate officer of the hospital service What, on the contrary, we ought to do, and must see that we do, is to strengthen his position as the person primarily and permanently responsible for the patient In a time of inevitable specialisation, the general practitioner alone has the opportunity to care for the patient as a whole, and it is for this difficult duty that he must be better armed

Cardiac Output and the Position of the Patient

WHEN those brought up in the clinical tradition believe that a quantitative method will provide an answer to the important questions that they are asking themselves, it is not surprising that they are sometimes carried away by the figures and ignore the ordinary precautions of quantitative work and the limitations of our present knowledge Thus it satisfied many to note that cardiac output fell by as much as a third when the recumbent was changed to the upright posture,[1] [2] for then the practice of nursing cardiac patients in a sitting position was confirmed and hallowed by the experimental method Cardiac catheterisation is now so universally practised that it is perhaps surprising that no planned experiment has been undertaken until recently to te the repeatability and to check the errors of a singl estimate of cardiac output The paper by DONAL et al[3] is, therefore, a particularly important significant contribution to our interpretation laboratory findings

Many factors, both known and unknown, combine to vitiate the results obtained in man (in none are these so numerous as in those medical knowledge) To enable comparisons to made either between repeat estimations in same patient or between different patients, it h become essential to minimise the effect of these fa by ensuring that the subjects of the experiment in a "steady state" and that both the procedur adopted and the accuracy of the methods used shoul be clearly defined DONALD and his colleagues carefully planned their work to this end The precautions and the steps taken to attain the steady state admirably set out and might well be taken as standar practice in any investigation requiring accurate stud of cardiac output Even with these precautions, th difference in cardiac output between two succ estimates taken at an interval of approximately minutes may be as much as 1 75 litres per min although in the majority of instances it was much Indeed, in those patients with a high output, difference of 0 1 vol. % in the A-V difference may reflected as a half-litre difference in the card output For the whole series the standard error of single estimate of cardiac output was approximate 8%—a finding essentially similar to that obtained COURNAND[4] from a selected, though not comparable, series of patients

Having established the quantitative measurements on a sound basis DONALD and his colleagues then provided data from which the effect of nursing positions upon cardiac output could be determined. It is pleasing to see published data from which the reader can draw his own conclusions and compare them with those of the authors—a practice which might with advantage be more frequently followed. They found that the effect of posture on the cardiac output was variable. In some subjects cardiac output remained unchanged, in some it rose, and in some it fell. In the whole group there was a mean decrease of 0·36 litre per min.; this decrease was statistically significant, but the authors consider it to be so small as to be probably unimportant. The 36 people studied included 10 normal subjects, 6 with a high resting cardiac index and 6 with a low cardiac index, 6 patients with mitral stenosis, and 8 with either cardiac or respiratory disorders. In a heterogeneous clinical group the mean results may bear little relation to the clinical significance of the findings in the various subgroups, and in selecting their subjects to cover all variables, DONALD et al. have necessarily had some difficulty in expressing their results, even though none of these subgroups behaved differently from the whole group. It is conceivable, for example, that in the group of patients who had lately been in congestive cardiac failure the work of pumping 0·36 litre per minute extra—500 litres per day—might be quite sufficient to cause the death of a patient on the borderline of congestive failure, if he was nursed flat—an unlikely event. The renal tubules excrete excess sodium long before changes can be detected in the plasma, and life is sustained on one or two microgrammes of vitamin B_{12} daily. It would not be surprising, therefore, if the body's homoeostatic mechanisms in the cardiovascular system were more sensitive than the present means of measuring them. If this is so, then it is unlikely that statistical analysis in a heterogeneous group can reflect the true state of affairs unless the number of subjects in the subgroups is greatly increased. This in the matter investigated by DONALD et al., would entail Herculean work out of proportion to the importance of the question posed—and these observations are applicable to many aspects of clinical research. DONALD and his colleagues have appreciated the difficulties and they have been conservative in interpreting their findings concerning cardiac output in direct relation to clinical problems.

That the measurement of cardiac output is at present rather crude is also suggested by the more consistent findings with pulmonary artery pressures and pulse pressures—measurements that are subject to smaller error. DONALD et al. found that in the sitting position the pulmonary artery pressures, in people with a high initial pressure, and the pulse pressures in the whole group fell. While it is readily understandable, though by no means proven, that symptoms are relieved by a fall in pulmonary artery pressures and by the consequent decrease in the demands on the heart, it is hard to understand the teleological reason for the fall in pulse pressure in the sitting position in normal subjects, seeing that most of us sleep flat. No doubt much more evidence will be forthcoming to answer these questions, but meanwhile the clinician may be relieved to know that it is justifiable to nurse his patients in the position they find most comfortable.

The Public's View of Tuberculosis

SURVEYS of public opinion, ranging from the housewife's view of foaming detergents to the mother's estimate of child welfare clinics, are as popular as ever. GORE and HARTSTON[1] have now given the results of a survey, made during the first quarter of 1952 by health visitors, of 1080 mothers of children born in the administrative county of London and in Tottenham during the fortnight ended Sept. 1, 1951. The aim was to measure the extent of the public's knowledge of pulmonary tuberculosis and to see whether people were aware of the facilities for the diagnosis and treatment of this disease. The inquiry was made among a readily accessible group of women who were to some extent selected in that they were the mothers of six-month-old babies and represented, therefore, only a small proportion of the whole female population. An earlier survey, carried out in the London area in 1950, was partly based on a questionary about tuberculosis which was put to 432 adults, a carefully selected "random" sample. This inquiry was also used to compare the reliability of those interviewers who were fully experienced in the technique of interviews with that of interviewers new to the work. An analysis showed that the responses obtained were sufficiently close to justify the use of amateur interviewers when these were easier to come by.[2] This finding is of importance when judging the results of the surveys made by students from the teaching hospitals as part of their public-health training—for example, a recent survey to assess the value of antenatal instruction and child-welfare clinics.

The tuberculosis questionary used in 1950 was used again by the health visitors in 1952. The first question dealt with the relative mortality of tuberculosis and cancer; 44% of those interviewed thought that tuberculosis killed most people in this country, and 35% considered cancer to be the chief cause of death. At the time of the survey 41% thought more about tuberculosis than about any other disease—nearly twice as many as those whose thoughts were more often on cancer. It should be noted that the early part of 1952 was not a time when poliomyelitis was *prominently in the public mind*. The confusion about tuberculosis is indicated by the fact that while 43% thought that the disease was hereditary, 44% believed it was not; and of those who said that it was not or did not know, 42% had no idea how the infection could be conveyed. Contrariwise, when asked if the disease was catching or contagious 71% said "yes" and 22% said "no". Of the 1080 women interviewed 66 said that there was somebody with tuberculosis in their family at the time, but 30% of this contact group did not think that the disease was infectious. This figure makes it clear that the instruction given by tuberculosis health visitors and chest physicians is not getting across or is being misunderstood by patients and their families. But 80% of the 66 women who were family contacts said that their chests had been radiographed, which indicates very efficient supervision of contacts either by mass X-ray units or by chest clinics, though 80% is probably

---

1 Gore, A. T., Hartston, W. *Mon. Bull. Minist.* *Serv.* 1953, 12, 131.

2 Durbin, J., Stuart, A. *J. R. statist. Soc.* 1951

higher than the proportion in the whole contact population. Few physicians at chest clinics would claim a supervision-rate as high as this The failure to examine all contacts may be partly explained by the fact that 69% of the women questioned thought that many people were afraid to be examined in case they had tuberculosis The sketchiness of the public's knowledge of tuberculosis was also shown by the finding that 54% of women knew nothing about the causes of extrapulmonary tuberculosis, and only 4% suggested that milk had something to do with it In several other ways the survey disclosed lack of information or failure to absorb it 80% had never heard of B C G vaccine, more than half realised that hospitals and sanatoria were provided for treatment, but only a quarter knew that priority food and milk were available for tuberculous patients On the other hand, 72% said that the present number of hospitals and sanatoria was insufficient to deal with a disease which 91% considered to be a serious problem and which 61% thought was more serious than poliomyelitis These results are very similar to those obtained by DAVID[3] in his analysis of the 1950 survey, with one curious exception in the answers to the question about symptoms Frequent cough was thought to be a symptom by 63% of the mothers and by only 35% of those in DAVID's analysis, 19% mentioned blood in the sputum, as compared with 8% in 1950, and 28% included loss of weight, as against 18% in the earlier figures Perhaps this difference was the result of direct questions at the antenatal clinic, but it may also be attributable to the valuable health teaching given by certain women's magazines

When, as the survey suggests, 80% of this adult population know where to go for an X-ray examination of the chest which 98% feel should be done regularly to combat a disease which 80% think is curable, which 91% believe is a serious problem to the country, and which 71% know to be contagious, it is disappointing that the spread of the disease has not been checked more rapidly Can it be because of the 69% who are afraid to be examined in case they have the disease? Or is there some error in the survey—not in the sampling, but in the method of interview? There is now some evidence from the interviewers, both amateur and professional, that the much-interviewed public, especially the housewife, is at last beginning to show some "interviewer resistance" No longer are questions answered with a simple spontaneity, but with some hesitation as if the speaker was considering whether or not the answer would please the interviewer, or weighing any indirect repercussions that might arise from the reply So it is becoming increasingly difficult to be sure that figures obtained in this way accurately reflect public knowledge and opinion But these latest results emphasise the importance of vigorous propaganda, and the best keynote in the campaign is the cheerful one that patients *can* be made well and restored to a normal life Using all the well-tried methods of advertising, backed by instruction through the press, radio, television, and cinema, the methods of prevention and the importance of early treatment can be driven home Although modern chemotherapy has greatly improved the chances of successful treatment, it has not detracted from the importance of knowledge as a means of prevention

Annotations

THE MEANING OF EDUCATION

THE hours we spent with dogfish and club moss nerve-muscle preparations, test tubes, cultures, microscope slides laid down in us patterns as lasting those in Pavlov's dogs Even if we have since be exponents of the art, rather than of the science, medicine our training has preserved in us some linger sense of proportion and discrimination when the scienti aspects of our calling are discussed This is something but as a preparation for life was it enough? Was i even thorough enough, let alone wide enough? D A T Macqueen[1] thinks not, and he urges the val of philosophy as a mind-widening discipline for student "Despite the lip service paid to the concept of tr the patient as a whole," he says, "too many med students graduate with the idea—which their teache do little to correct by philosophical teaching—that ma is little more than a collection of basic particles, built into cells and organs, which needs occasional techni repair and a lot of humouring" There is no cohere theory of medical philosophy, yet (as academic phil sophers are always trying to point out) all men a applied philosophers, none more so than doctors, every decision, every word of advice given by doct implies a philosophy, an attitude to man, to human and duties, and to the universe as a whole If do themselves have no clear notion of their philosophy diverse and random impressions must they leave their patients, and what vast tracts of their pat minds and natures they leave unexplored

The idea of learning philosophy—and its companion, logic—does not readily commend itself doctors Scientific method, we are apt to think, is should be—a better training for the mind than logic was As for the relations of man to God and the unive and all that, the attitude proper to a scientist is cism In modern education, however, and espe perhaps in medical education, the opportunities hearing what great minds in the past have thought ab such topics are so few that our attitude of might strike an informed observer as one of Medical ethics are no more self-evident than any kind of ethics What is a "right" or a "wrong" (or professional) act? This is a problem in app philosophy, yet our universities seem to assume that medical student can solve it without formal or any encouragement to consult published Certainly many doctors (like many other univ students) cannot distinguish between a primary and secondary cause, and here Dr Macqueen refers us examples to *The Lost Tools of Learning*,[2] a paper read Miss Dorothy Sayers to a vacation course in ed few years ago She illustrates not only such failures discrimination, but also the common trick of ass the thing we set out to prove Modern education, argues, does not teach us how to learn we rem what we have learnt, but forget altogether how learned it, and she believes that medieval schemes education did the job rather better For the syllabus divided into two parts, the *trivium* and the *quadrivi* and the whole of the first part (the *trivium*) was with teaching the pupil how to think and how to lear how to use his tools, in fact

The *trivium* consisted of grammar, dialectic, rhetoric, in that order, which fitted themselves well, she says, to three stages of childhood—the "p parrot," the "pert," and the "poetic" G meant learning (at an age when glib learning is easy) structure of a language—usually Latin—and later to use language: how to define terms and make accurate statements, how to construct an argument and detect fallacies, one's own and other people's Dialectic embraced logic and disputation—both well suited to the pert age in which the young are fond of contradicting, answering back, and catching other people out Since the nuisance value at this age is in any case high we may as well canalise this natural argumentativeness she thinks, *by teaching children to argue rationally* accurately, and persuasively, and at last to defend a thesis publicly against critical opponents Graduating from this to the age of rhetoric—the poetic age—the pupil had thrown open to him the world's store of knowledge and with the tools of learning now at his disposal he could pursue his studies appreciatively and critically, fitting himself for the *quadrivium* the university course

---

[1] *Universities Quarterly*, May, 1953, p 298

[2] London Methuen. 1948 Pp 30 1s

There is room in such a scheme Miss Sayers points out, for a liberal education for the mind needs to be exercised on other things besides Latin grammar—on verse and prose myth and legend, history, geography natural science mathematics, and theology ' It is in the highest degree improbable, ' she admits at the outset of her paper " that the reforms I propose will ever be carried into effect." Yet she persuades us to pause and consider how valuable such an education would be for those coming up to the university to study medicine. They would take to scientific method like mercury to metal; they would be able to define terms, to detect fallacies to express themselves ably and unselfconsciously to argue rationally, to write at least one language well and to light their own field with some glimmerings from the world's literature. These are benefits we cannot hope to see in our time; but it is surely possible to find opportunities, in the medical curriculum to give our students some sense of cosmos, some realisation that medicine is a small province in a universe of learning

OPERATIONS ON THE AGED

THE proportion of old people among the population of civilised countries has been increasing for fifty years and, unless some unforeseen factor intervenes, it is likely to go on increasing in the immediate future The surgeon must therefore deal with an increasing number of patients in the older group and it is important to determine whether an operation on them carries increased risks and, if so, what precautions should be taken to avoid these risks.

The question is well discussed in a recent paper by Cole.[1] Basing his conclusions on a consideration of 656 operations performed at the Illinois Research Hospital Chicago from 1948 to 1952, he gives a very hopeful outlook for those over the age of sixty who have to undergo operation There were 2557 patients under sixty, and 1090 over that age The mortality rate for major operations was 2 07% in the younger group compared with 2 95% *in those over 60* There was no significant difference between the groups for the operations of radical mastectomy, cholecystectomy colectomy gastrectomy herniorrhaphy and thyroidectomy but the older group did not do so well after œsophagectomy pneumonectomy excision of the rectum and radical operations on the mouth and neck.

The results achieved by Cole and his colleagues are astonishingly good for the figures given by other surgeons are by no means so encouraging but every surgeon will agree that the prospect of success in operations upon old people is today very much improved by the greater care taken before and after operation, the better methods of anæsthesia, and the advances in operative technique and in combating infection Perhaps full advantage is still not being taken of these benefits Flemming[2] has found that fractures in the old are still treated less thoroughly than they should be, and that thus the patient may suffer avoidable disability and a hospital bed may be occupied needlessly long

Older people differ greatly in their reactions to operation A man is as old as his arteries they say, and the elasticity of the arteries diminishes at a varying rate in different people but, generally speaking the surgeon can operate on older people with comparative safety if certain precautions are taken Any anæmia or an inadequate blood volume must be corrected and hormonal deficiency made good The blood protein and non protein nitrogen should be determined, and the serum levels of sodium potassium, and chloride estimated and any imbalance corrected Before operations on the biliary tract the hepatic function should be examined and in patients with heart-disease it is important to know the cardiac reserve Cole states that in some instances a very bad general condition can be much improved by giving 100 mg of corticotrophin (A C T H) daily for five days before operation. His wise advice is that ' the surgeon should be prepared to choose a shorter procedure, or perhaps adopt a stage procedure if the patient's condition should deteriorate significantly during the operation. '

With modern methods of anæsthesia postoperative chest troubles are rare but in the aged deep breathing exercises are a particularly valuable guard against pulmonary collapse and aspiration of the bronchi by tube-suction or bronchoscopy must be performed at once if collapse does occur Early ambulation may prevent thrombosis but in feeble patients this may be impossible After all one must make some concession to age

SAFE CUSTODY

CUSTODY is a word which has got into bad company It began kindly enough by meaning safe keeping protection ' "charge,' care,' guardianship That was in 1491, but in the early 17th century it started to form associations with confinement, imprisonment,' and durance. Even nowadays, when we use the term, we think more about the safe keeping of society than of the person taken into custodial care—who may be a sick person or a child

In an erudite study of the word and its influence on practice, Dr John R Beith Robb[1] physician superintendent at Woodilee Mental Hospital Lenzie Glasgow argues for a scientific understanding of the custodial relationship in order to place that relationship on a more civilised level He gives examples from Scotland in the 18th century, showing how failure to define the word custody, and its abuse, left prisoners with no redress for inhuman treatment The word in its crude sense has been carried over to other closed communities—he cites the old Bridewells, workhouses and recent concentration camps For the purpose of his analysis of the degradation found in these closed communities he defines custody as *that relationship which arises* when one person the Custodian gains power over another person animal or thing irrespective of purpose and with or without legal authority Since such a relationship can become depraved, reformers have continually demanded that it should be regulated by statute Legal enactments, however use the terms safe custody strict custody ' and place of safe custody without clear definition of these words The interpretation that ' safe custody means safe *from* escape is that of the 18th-century gaolers This interpretation Dr Robb whole heartedly rejects claiming that safe should mean safe from the risks of degradation "

Having classified public laws, over a period of 2000 years according to risk, he finds that legislators have been endeavouring to contend with five types of risk—namely vice, ignorance, disease, violence, and property risks Dr Robb holds that these risks are not only inseparable but are all transmissible to the society in which the individual affected—whether as victim or aggressor—is transferred This constellation of risks he describes as "degradation" Perpetrators and victims of risks have at all times been removed from the community at large and placed in closed communities, the risks travelling with them Institutions which have no proper facilities to prevent the spread of the risks imported into them become slum institutions and unfortunately this type of institution is quite common throughout the world

[1] Cole, W H *Ann. Surg* 1953 138 145

[2] Flemming C. *Lancet* 1951 i, 758

[1] *Surgo* (Glasgow University Medical Journal) 1953 19 121

In a State service, where great numbers of administrators and employees have been given authority over greater numbers of persons in public institutions, a group custodial relationship arises Yet it is not clear who are the persons responsible for the safe custody of people in public institutions If, on occasion, the obligation of trust fails, the tendency is to name some official as responsible, even though that official may have no executive powers Dr Robb contends that an anti-degradation philosophy must be accepted at the highest official levels before it can permeate to subordinate staffs, because the physical means of guardianship are ultimately controlled at the higher levels An anti-degradation policy demands that institutions should be constructed to facilitate the work which must be carried out in them Architects in the past have designed and erected the most unmanageable of buildings, many of which are still occupied In such badly designed places, there may be provision for medical treatment and an abundance of kindness, and yet custody may be far from safe We share warmly his opinion that the architects and also the servicing departments should thoroughly understand the anti-degradation philosophy

Dr Robb concludes that where the words "safe custody" appear in an enactment dealing with a public institution, the interpretation of "safe" should mean "safe from the risks producing degradation" He warns that "strict custody" always tends to be dangerous, so all who are directly or indirectly responsible for the custodial relationship are under an obligation to cooperate for safety Public institutions might then approximate to that state which the law styles as "places of safe custody" irrespective of the specific purpose of the institution

FIRST STEPS IN EMBRYOLOGY

WE shall probably never be exactly certain of what takes place in the darkness of the human fallopian tube when the ovum is fertilised, but the last few years have seen a steady accumulation of indirect information which enables us to make a reasonable guess Circumstantial evidence is here, as often in the law court, almost as valuable as an eye witness account The latest weapon to be turned on this fundamental target is the phase-contrast microscope By its use, Odor and Blandau[1] studied the changes in living rat eggs removed from the fallopian tube, and the behaviour of spermatozoa in relation to them Now Shettles[2] has applied this technique to human ova removed at operation either from the ovarian follicle or from the tube, and he has taken some remarkable photographs The ova were exposed to semen in vitro and incubated at 37°C for varying periods Shettles finds that the corona and cumulus cells are rapidly stripped off a follicular ovum when small pieces of homologous tubal mucosa are added to the preparation, this stripping is not effected by hyaluronidase or by semen alone He failed to observe any evidence of a specific attraction of the ovum for the spermatozoa, though those which come in contact with it by chance become fixed to it In vitro the ovum can apparently be penetrated by several spermatozoa, though whether this occurs in vivo is uncertain. It also appears that the whole spermatozoon may remain intact after penetration of the ooplasm, as has been reported in several mammals

Such studies, carried on under artificial conditions merely indicate probabilities, but they confirm that human as well as mammalian ova can be used to give information about the process of conception The e work of Hamilton[3] in this country and Rock and his colleagues[4,5] in the U S.A is thus being extended, and phase contrast microscopy has now proved its value investigations of this kind

RECURRENT PAROTITIS IN CHILDHOOD

THE pioneer work of Payne[6] in the '30s added much to our knowledge of recurrent parotitis, but this disorder, which is by no means rare, continues to pass unrecognised Published accounts of it are few, the largest series of cases in children was published in the States by Bigler[7] a few years ago Attention has been drawn to it by Everley Jones,[8] who describes cases in children observed over a period of five years the Midlands

Recurrent parotitis shows no decided age distribution though it is probably commoner in adults than children In children it seems to be equally co in each sex, but among adults it is much commoner women than in men The principal clinical feature swelling of one or both parotid glands, recurring one more times The whole gland enlarges and is usually tender, and when recurrences are frequent some enlargement may persist between exacerbations The frequency of recurrence may vary from weekly to yearly In the active phases there is always some discomfort, and usual pain which may be severe In most cases the orifice Stensen's duct usually looks normal, but in very acute episodes redness and swelling may be seen around Turbid saliva can nearly always be expressed, while severe cases purulent saliva can occasionally be seen drip from the duct orifice In most cases the secretion produces the "snowstorm" effect described by Pa, this is caused by small accretions of cells and mucous casts of ducts, suspended in turbid saliva Calculi not formed The diagnosis is confirmed by sialog This valuable investigation, developed by Payne, r characteristic changes which Everley Jones found in of the 14 children in whom it was done When sial graphs are taken after injection through a blunt nee of 1–2 ml of a radio-opaque fluid into Stensen's spherical dilatations of the finer ducts are displ, occasionally dilatations, usually fusiform, are seen in the main ducts The dilatations are sometimes mental There may be no fever, and the white blood-count is usually only slightly increased Payne ob that patients with recurrent parotitis are in g constitutionally nervous, and he suggested that instability of control of salivation via the cranial autonomic sys might be a causal factor

As in other series, Everley Jones isolated α haemoly streptococcus (*Streptococcus viridans*) from the ma, of his cases, this organism was found alone in 12 and association with a pneumococcus in 3, while a pneu coccus alone was isolated in 2 The pneumococcal which seem to be relatively commoner in children th in adults, are usually more severe than the streptoc and suppuration may occur, but rupture through parotid fascia is rare Pathologically the disorder mild chronic sialodochitis with recurrent exacerbations which lead to attacks of subacute parotitis

It may seem strange that this disease rarely affects the other salivary glands. In Payne's series of 52 cases of recurrent sialadenitis the parotid glands were affected in 50 cases and the submaxillary glands in only 2 Dissimilarity in structure and function are thought to be the *reasons for this selectivity the parotid glands are* entirely composed of serous acini drained by long narrow ducts—even Stensen's duct is narrow—whereas the mixed serous and mucous acini composing the submaxillary and sublingual glands are drained by wider ducts Infection of the parotid glands is undoubtedly facilitated by the greater tendency to stagnation of the secretion and the presence of only a small amount of bactericidal mucus in the secretion A source of infection in the mouth nose or throat such as carious teeth or septic tonsils, is found in a significant proportion of cases There is no doubt that almost all forms of acute and subacute parotitis are caused by ascending infection Bruce Pearson[9] described 11 cases of recurrent parotid swelling in children in which there was no evidence of infection but usually there was a history of allergy and he believed that allergic swelling causing obstruction of the duct produced the parotid enlargement

Recurrent parotitis is usually regarded at first as mumps but once there have been several relapses the diagnosis becomes clearer Acute staphylococcal parotitis, which soon gives rise to pus and is not recurrent, and neoplasm sialolithiasis, and sarcoidosis which have distinctive features and are rare in childhood are unlikely to be confused with recurrent parotitis. Treatment should consist in eliminating septic foci in the mouth nose and throat—notably carious teeth and infected tonsils All workers agree about the importance of massaging the gland towards the duct orifice, to counteract the tendency to stagnation of secretion which increases with infection Massage should be done before and after each meal and also in the morning and at night. Instillation into Stensen's duct of penicillin or other antibiotic to which the infecting organism is sensitive is usually helpful though it does not as a rule bring about immediate cure Assessment of results is difficult because spontaneous recovery is possible; but in Payne's series before the introduction of antibiotics the average duration of the disease was nine years.

THE TELL-TALE HEART

READERS of Poe will remember the murderer who buried the corpse under the floor but was undone by his victim's heart, which obstinately refused to stop beating and moreover did so with such loudness that it drove the unhappy slayer to madness and confession Such an audible manifestation of cardiac activity is rare even in life and this is perhaps fortunate for otherwise systolic pinking due to low protein octane-rating might well have become part of modern advertising mythology *Occasionally however disease of the heart* or lungs may produce sounds which can be heard with the unaided ear at distances from a few inches to several yards away Bean,[10] of Iowa, has lately collected from his own and from published records 164 instances of this unusual and interesting phenomenon In about one third of the cases described the audible sounds were in fact very loud valvular murmurs usually produced by free aortic regurgitation These are variously described as 'croaking' 'humming' 'whistling' or cooing or some other musical term Pneumothorax or interstitial pulmonary emphysema, either traumatic or spontaneous account for another third and in such an event the sound is usually said to be clicking crackling or "bubbling Pneumopericardium is a less common cause of similar noises. A loud "mill wheel' murmur may be produced by the churning of blood and froth in the right ventricle after air-embolism Hiatus hernia sometimes seems to act as a sounding board for the heart and occasionally a normal stomach distended with air and fluid may do the same thing Very rarely audible heart sounds without apparent cause have been recorded

Loud heart sounds are usually not in themselves of great consequence but they may be alarming and disturbing to the patient Anxiety can usually be dispelled but the disturbance of sleep may be troublesome Bean tells a sad story of an unusual affair of the heart a young man was banished by his wife to the spare bedroom because his heart kept her awake but fortunately the disturbance proved transitory

EPILEPSY OF LATE ONSET

THE onset of fits in middle and late life always raises a diagnostic problem Since epilepsy is a symptom quite as much as a disease sui generis there is always the possibility of some underlying progressive cerebral lesion even when there is evidence to suggest a constitutional predisposition The view that a progressive brain lesion in particular a neoplasm is responsible for the majority of fits coming on in middle age is still widely expressed in medical textbooks and Penfield[1] seems to give it his support But there is now evidence against it Nattrass[2] followed up a group of patients whose fits started at 40 or later and he found no evidence of progressive brain disease in the majority of them Berlin[3] supports this finding by his series of 125 men whose grand mal seizures started at the age of 35 or later 59 cases were followed for less than three years 30 for three to seven years 21 for eight to fifteen years and 15 for sixteen to twenty five years No evidence of general or neurological disease to account for the seizures was found in 84 patients, while in 40 others severe closed head injuries cardiovascular disease, or alcoholism were considered to be at least partly responsible Indeed many neurologists would agree that the grand mal seizure at any age without focal aura or focal onset, is more likely than not to belong to the group where no local lesion can be found

The question remains how far in a given case we should pursue the search for a possible progressive brain lesion which may be accessible to surgical treatment Most physicians would be content with the findings of a thorough neurological examination, an X ray examination of the skull and a carefully planned electroencephalogram in the elderly patient, with evidence of vascular changes, who had a few isolated fits If fits increase, however or the patient is rather younger and there is nothing to suggest vascular change the question of examination of the cerebrospinal fluid (C.S.F) and air encephalography or angiography will sooner or later arise If the C.S.F is abnormal then encephalography should be done unless there are special reasons against this *investigation, such as the general condition of the* patient or evidence of raised intracranial pressure Further if the fits are focal in onset or have a focal aura then carotid angiography on the appropriate side should be undertaken: for focal fits in the middle aged usually indicate a local, though not necessarily progressive lesion Their significance is quite different in infancy or early childhood when a focal onset to convulsions of any sort is far more common When the C.S.F is normal the value of intracranial air studies is doubtful Marshall and Whitty[4] for instance, found that in 52 Service patients, who had their first fit between 20 and 40 years of age and who showed no abnormal neurological signs, air encephalography was of no further diagnostic value Berlin's findings are similar of 57 patients on whom air studies were performed, only 1 showed a localised abnormality—a traumatic cyst, known to be of some years' standing—and only 4 others showed significant generalised ventricular dilatation Moreover, in reviewing another group of 81 proven cases of supratentorial brain tumour, he found that 3 had normal air pictures one year after the onset of epilepsy, and another 1 four years after the onset

[4] Marshall, J., Whitty C. W M. *Brit. med. J* 1952 i 547

The facts certainly cast doubt on the value of this investigation in grand mal epilepsy without focal signs On the other hand, the diagnostic value of focal fits or the presence of focal signs is well illustrated, for in Berlin's series of subsequently proven brain tumours presenting with epilepsy, 59% had jacksonian attacks, and in 85% either jacksonian attacks or neurological signs of a focal lesion developed within a year of their initi l fit These figures support the growing impression amongst neurologists that epilepsy of late onset may still be of "idiopathic" type with a relatively good prognosis This does not relieve us of the necessity of investigating such cases fully, because the occasional slow-growing neoplasm, which does present in this way, may be readily and successfully treated Negative findings from a full investigation enable the clinician to give a reassuring prognosis with added confidence, and continuing freedom from a focal element in the pattern of the seizures, and from neurological signs, suggests that this confidence has been justified

NEW OPTICAL AIDS

MANY of the partially sighted can read comfortably if the type is large enough The National Institute for the Blind has done much research on the use of large types, and its committee on the education of the partially sighted found that books in 18-point type—

that is, in type of this size—

could be read comfortably by most of the children tested The cost of producing enough books in this type is prohibitive, however, and the same applies to books reproduced in large type by 'Photostat' In 1946, a joint committee of the Institute and the London County Council was appointed to advise on the use of optical aids for this group of handicapped people, and has now reported[1] The committee concentrated on magnification by lenses or projection, and on handwriting When part of a page of type is seen with both eyes through a lens, two monocular images, which do not coincide, are formed One of them is farther from the lens than the other, and displaced to one side of it Moreover the distance separating the two images varies as the sight sweeps across the lens from one side to the other The eyes have thus to make constantly changing efforts at accommodation and convergence, in the attempt to fuse the two images into one In some people this causes headache and eye strain, but the committee says this is not necessarily harmful It was decided, however, to experiment with lenses of greater magnification and a wider field of vision than any on the market With the coöperation of the research department of Imperial Chemical Industries Ltd, two aspheric plastic lenses were produced, one $4^1/_2$ in in diameter, the other 6 in, and both having a magnification of 3 with focal lengths of 6 in The magnification was satisfactory but the distortion and chromatic aberration could not be quite overcome with lenses of this type Nevertheless plastic lenses—once the mould has been made—can be produced very cheaply, though they are, however, easily scratched They can easily be protected by two sheets of plain glass, but these introduce annoying reflections In the earlier models, electric lamps were fitted along the stand, so as to shine on the page, and coloured fil were often used to cut down glare, for this amber seemed to be the most satisfactory colour fluorescent lighting was introduced, however, these reading lights proved unnecessary, since it was pos to get good illumination throughout the school they carried, in any case, the inconvenience that had to be fitted to every desk

The aim of the committee was to examine capable of covering the whole width, and half the of a page of an average size book, and they studied lenses in particular

The 'Lenslite' (glass), 8 in focal length, plano-magnification 2 5

The 'London' or 'E D L.' (glass), 11 in focal length, bicon magnification 1 9

The 'Britex' (plastic), 10 in focal length, asph magnification 2

These were tried in schools for the partially sighted, it was found that the children liked the 'London' the 'Britex' about equally, and better than the lite' These were children whose visual acuity ra from $^3/_{60}$ to $^6/_{18}$, though most of them had less than They were also tried with binocular loupes, consistin a pair of spherical lenses worn as spectacles over ordinary correction spectacles, with the bridge of loupes resting on the lower part of the nose The pa lenses forming these loupes are as though taken from edge of a single large lens, and as a result there is a optical centre, and the reader does not have to make effort to converge the eyes to look at a page held at focal length of the lens combination (The magnific is about 2) Loupes of course, can be carried about easily than lenses mounted on a reading stand, and draw less attention to the user The children, how did not show any particular preference for the over the mounted lenses

Magnification by projection can be achieved either enlarging the projected print by means of lenses, with without mirrors, or by microphotography of pri reading matter, which is then projected on to a The first is done by the various types of episcope (w project on to a screen at a distance from the appara and also by other devices which, by a system of project the print on to a ground glass screen conta in the apparatus itself The magnification, with types of apparatus, can be varied—with the episcope varying the distance of the projector from the and in the combined units by the choice and positio of lenses Any printed book can be read with these of apparatus, but the contrast between the print background is poor, and the machines are expen Moreover, it is hard to get the pages of the book flat there is some distortion, and every time a page is tur the book has to be adjusted so as to bring the first into the correct position for reading Print can also photographed on to a microfilm and projected on screen, this device has been developed in America patients obliged to lie flat in bed the print is pro on to the ceiling, and a simple switch panel, managed the patient controls the movements of the film films are 100 ft long and carry 1600 pages, which from right to left[2] An apparatus of this type was insta last year at the Miller General Hospital, Greenwich[3] joint committee is conducting experiments to assess value of these microfilm projectors for individual, for class, use

Coloured "blackboards," and different-coloured have been used in some schools to help partially sig children to read handwriting easily The children in school prefer blue chalk on a yellow board, but vary

Public Health

AN INFECTIOUS DISEASE INTELLIGENCE SERVICE

A W S THOMPSON
O.B E. M B Edin. F.R C.P.E. D P.H.
MEDICAL OFFICER OF HEALTH AUCKLAND NEW ZEALAND

IN a country like New Zealand where the local health departments administer the social security medical scheme contacts between general practitioners and the medical officer of health are liable to be of a somewhat unpleasant kind In my own district which covers some 000 sq miles and has a population approaching 450 000, there are over 400 doctors in private practice, and it is impossible for the M O H to know more than a few of them well In such circumstances the doctor's most frequent reminder of the existence of the health department is apt to be an inquiry about his claims for payment from the Social Security Fund As a result he comes to regard the M O H as a snooper and checker of forms rather than as a colleague who happens to be a whole time officer of the social medicine services Two years ago I began an experiment in coöperation between general practice and public health and this has been so successful as to seem worth describing

An Experiment in Coöperation

I began by getting in touch with 10 general practitioners scattered about the city area of Auckland. I explained to each that I had felt for a long time that my department was not sufficiently in touch with the work, thoughts, and opinions of the general practitioner At the same time we had no means of collecting accurate information about the prevalence of non notifiable diseases such as measles whooping-cough diarrhœa, and vomiting I invited the doctor to become a member of an unofficial group of practitioners who would send me each week a voluntary return of the numbers of new cases of certain diseases seen in the past seven days with comments on other illnesses prevalent among their patients On my side I would let them have each month an analysis of the returns from the group with any other useful information about illness in the city which came my way from other sources I also suggested that we might meet together once or twice a year to review our work and discuss matters affecting general practice and the health department.

Rather to my surprise I met with no rebuffs. Every doctor I approached agreed to join, and none of them thought that the preparation of a weekly return would be very difficult or too much trouble

The first meeting of what we now call the Medical Practitioner Group was held on Nov 31 1951 After talking over the plan for setting up an infectious disease intelligence service we had a general discussion about illnesses prevalent in Auckland at that time. We went on to consider some health department activities in which the general practitioner was interested. These talks were so stimulating that it was decided to meet again the following month and we have been meeting once a month ever since At the second meeting I thought it wise to point out that I had not formed the group as an advisory body to guide the policy of the local health office. I was anxious to obtain through the group opinions on various matters concerning the health department and general practice and would carefully consider them but I did not undertake to accept its guidance where they conflicted with my own convictions. On this basis the group has functioned very happily

WEEKLY REPORTS

The practitioner makes his weekly report on a cyclostyled sheet with the following sections:

1 Total number of *new* cases seen in last seven days
   Chickenpox
   Mumps
   Measles
   German measles
   Bornholm disease
   Acute laryngo tracheitis
   Whooping-cough
   Infective hepatitis
   Diarrhœa and/or vomiting
   Influenza
   Otitis media
2 Notes on D and V cases *Impressions* of age-groups mainly affected type severity &c.
3 Note on types of influenza.
4 Other prevalent illnesses and remarks

Two further items were added later because of current *developments in the city*

Infective hepatitis.—Please give name and address of any case of jaundice with history of blood or plasma transfusion in past 18 months

Acute nephritis —Please list any definite cases, whether sent to hospital or not.

Herpangina has now been substituted for acute nephritis in the weekly returns

Before the end of every month forms for each Friday in the next month are posted to the doctor, each having a stamped addressed envelope clipped to it. He asks his nurse to place the appropriate form in front of him every Friday afternoon, for completion from the notes which he keeps in his pocket-book If the doctor is away the form is sent in by the nurse suitably endorsed To preserve uniformity and accuracy information from locums or assistants is not asked for obviously some locums would be less enthusiastic about this than others

At the office my personal clerk checks the forms in each week and reminds the doctor's nurse by telephone if any do not arrive promptly When this happens it is usually due to an oversight; somebody has forgotten to post the envelope One member of the group was ill for the greater part of the first year, another who had to resign owing to overwork was not replaced immediately and most were off duty at some time or another but we have averaged more than 8 completed returns each week in the first twenty months. In the monthly analysis all figures are "stepped up" to show the calculated numbers of cases for the whole group of 10 doctors, so that direct comparisons can be drawn from week to week. There are 114 general practitioners in practice in the city and the group handles about a twelfth of the work of the area. Multiplying their figures by ten therefore gives a fairly reliable conservative estimate of the prevalence of diseases in the community—or at least of the cases seen by doctors

MONTHLY SUMMARY

The monthly summary includes a table of the figures for the year up to date, and a digest of the notes and comments by doctors Charts showing the prevalence of certain diseases week by week and their distribution by the areas covered by members of the group are kept in my office. In 1952 there were rather severe epidemics of influenza and mumps and as the observers are dotted more or less from west to east across the city the spread of each disease could be traced as well as its general incidence

Discussion

The value of this experiment from my point of view can hardly be overstated It is a good many years since I gained my own small experience in general practice and that was not in New Zealand Now at least I can learn by regular friendly personal contact what the practitioner is thinking and what difficulties he is meeting with

Now and then I send out a circular letter to all practitioners in the district containing information about prevalent diseases new health department facilities, and so on These letters seem to be well received From time to time information obtained through the group can usefully be sent out in this way In July last year, for instance, many cases of acute nephritis were being treated in hospital, and I learned from the group that about six patients were being looked after at home for every case sent to hospital In some children hæmaturia had been noticed for several days before advice had been sought A letter giving details and emphasising the importance of absolute rest from the onset was sent out to all doctors, and a little later warnings were published in the newspapers Civilian epidemics of acute nephritis are rare, and even in this considerable outbreak most doctors saw only a few cases Several doctors told me later that it was only after getting this warning that they realised what was going on—one of them in the case of his own symptomless hæmaturia

Except in emergency it is best to let the profession have information of this kind in advance of the general public, but when any infectious disease is unusually prevalent I give a monthly statement to the press

The onset of a new epidemic of poliomyelitis was heralded several weeks beforehand by suggestive illnesses reported in detail by members of the group Toxic labyrinthitis, otitis media, and a vesicular pharyngitis, which may be related to the "herpangina" of the Coxsackie virus, have been shown to be remarkably prevalent Bornholm disease and infective hepatitis are being watched Acute laryngo tracheitis, a fairly recent immigrant, has just been added to the weekly report list It is obvious that there is plenty of material here for speculation and research

Quite often a medical officer of health gets a telephone inquiry from a newspaper office about an outbreak of measles, mumps, influenza, or some other non notifiable condition How humiliating it is to have to explain one's ignorance of the situation ! With this scheme in operation it is very different We not only know what is going on, and can hazard estimates of the distribution and extent of any outbreak, but if there is any unusual illness in the community we have a means of getting reliable information at very short notice

Our records should also be useful in time to come if it is desired to ascertain, for example, the influence of the minor epidemic diseases on pregnancy With some diseases, such as rubella, this method of estimating prevalence is probably more accurate than statutory notification, which is notoriously unreliable for diseases not treated in hospital

The enthusiasm of the group seems to grow from month to month, but membership has been limited to 10, not only because that number makes it easier to circulate information and maintain personal contact, but because enthusiasm too widely diffused loses its virtue As time goes on members will be lost for one reason or another, and replacements of equal energy and spirit may not be forthcoming But already the experiment has shown that one kind of cooperation between general practice and the health department which I had not thought possible under present conditions can in fact be achieved

The formation of a discussion group was not a definite part of the original plan, and I do not know how it will eventually work out We meet at 8 30 P M (nearly all New Zealand doctors have an evening surgery) and we made it a rule that meetings would close at 10 30 P M , but discussions generally end on the pavement We have no fixed plan, so far we have met often because we wanted to get on with the subjects we were studying, and that may or may not continue We have already published two articles (" Social Security and the Family Doctor" and " Financial Aspects of City General Practice Today ")[1] and a third is in preparation

For me these meetings are both enjoyable and stimulating, and I have been surprised and gratified that men who work so hard are willing to give up so much of their time There is no better doctor than the good general practitioner, and no better man When we in the public health service find means to tap this almost untried source of inspiration and enlightenment we may at last be able to show that social medicine has a real meaning

I wish to thank Dr J Cairney, director general of health, New Zealand, for permission to publish

---

Call for a Unified Service

At a meeting of the Society of Medical Officers of Health, held in London on Sept 17, Dr Andrew Toppin, the outgoing president, inducted as his successor Dr G Metcalfe Brown

In a presidential address, Dr Metcalfe Brown discussed possible developments in the public-health service and considered how the three separate divisions of the National Health Service might be modified and ultimately fused

Centralisation of government, he declared, had greatly weakened local government, with consequent reduction in efficiency and a danger of runaway national finances One suitable method of reform would be to create in the United Kingdom about fifty all-purpose local authorities, which would also be local health authorities administering the hospitals and consultant service, the general-practitioner service, and the public-health service The local authority should be composed entirely of elected members, and the medical profession and other professions should be represented by cooption to the appropriate local-authority committees, the final decision resting with the council composed entirely of elected members

Turning to the functions of the Ministry of Health, Dr Metcalfe Brown expressed regret that many of these had been dissipated For instance, the responsibility for housing, which today was the greatest public health problem, had been transferred to the Ministry of Housing and Local Government, and central control of duties relating to deprived children was exercised by the Home Office The Ministry of Health had been at its best when its duties were advisory and supervisory, but not executive

" The administrative reform of local government and the absorption by large local authorities of the present functions of regional boards, boards of governors, and executive councils would remove the large executive functions of the Ministry of Health and allow it to concentrate on its true function "

Of the hospital and consultant services Dr Metcalfe Brown said that the separation of teaching from other hospitals administratively was a mistake, and Scotland had done well to avoid this

" To base hospital administrative regions on university towns—and therefore presumably on the medical teaching schools of the universities—was as illogical and unsound as it would be if a large industrial undertaking were to base its executive administration on its apprentice training school

The administration of all hospitals by a small number of large local authorities would ensure the best use of hospitals beds, would guarantee continued clinical freedom, and would eliminate the present waste in relation to hospital administration

Dr Metcalfe Brown said that the widening of the interest of the general practitioner, and the need for preserving the continuity of medical care made a clear case for placing part of the hospital facilities under his direct control, and a unified administration would make this administratively easy

Short-term adjustments should include the return to existing local authorities of institutions for the care of the mentally defective In the tuberculosis service the local health authority, which was already responsible for domiciliary prevention, should, pending general reorganisation, take over clinical supervision in the tuberculosis clinics and the homes With regard to infectious diseases, administrative adjustments should be made to obviate the dangers of the system by which cases of infectious disease could be admitted to, and discharged from, isolation hospitals without the immlate knowledge of the medical officer of health who as responsible for prevention

---

[1] Auckland Medical Practitioner Group N Z med J 1952 51 332 Ibid 1953 52 200

Touching briefly on industrial medicine Dr Metcalfe rown suggested that this should not be a separate stem, which would add to the existing disunity and igh cost of administration

> Industrial medicine is not a separate subject—it is but ne of the many applications of general medicine and public ealth. The few specialists who exist in the field of -called industrial medicine are very necessary—e g, the xpert on poisons used in industry; but surely he is a specialist toxicology not a medical officer in industrial medicine

At the meeting members rejected by 78 votes to 31 a roposal to change the name of the society to the Society f Preventive Medicine.

Poliomyelitis

A W H O expert committee which has been meeting Rome to prepare a world programme of research to the disease last weekend issued a summary of its ndings

The *Times*[1] reports that the committee recommends hat research laboratories should be set up on all ontinents under the general supervision of W H O o identify, type, and study strains of poliomyelitis irus, as well as to provide materials for diagnostic urposes in all laboratories participating

The committee declares that the virus enters the body hrough the mouth, and that the primary site of infec ion is the alimentary tract Poliomyelitis is a highly nfectious disease spread by intimate association with nfected persons."

The committee, having studied the factors predisposing to or precipitating paralysis, suggest the following precautions: (1) that operations for removal of tonsils and adenoids should be avoided during epidemics (2) that the activities of people with an illness suspected of being poliomyelitis should be restricted for a week (3) that people intimately associated with cases of poliomyelitis should take the minimum amount of exercise from 5 to 21 days after exposure, avoiding fatigue from any cause including travel

In epidemics the public are advised to take the following precautions (1) to wash the hands before eating (2) to keep flies away from all food and to wash thoroughly all uncooked food such as fruit and vegetables (3) to avoid intimate association (shaking hands, using common utensils, common towels &c) with members of a family in which a case of poliomyelitis has occurred within three weeks; (4) to treat all febrile illness with caution and (5) to avoid all over-exertion

The general movement of people into and out of communities where the disease is prevalent should be discouraged; but schools need not be closed nor public gatherings forbidden. Swimming pools with adequately chlorinated water should not be closed, but they should not be overcrowded

NOTIFICATIONS IN ENGLAND AND WALES

Poliomyelitis notifications (uncorrected) in the week ended Sept 12 (30th week of the year) were as follows paralytic 92 (123) non paralytic 81 (101); total 173 (221) This is a decrease of 51 compared with the previous week the figures for which are in parentheses This fairly sharp fall suggests that the peak of the outbreak has been passed

International Conferences

NEUROLOGY

THE 5th International Neurological Congress was held n Lisbon from Sept 7 to 12, under the presidency of Prof. António Flores. The British delegates were headed by Sir Francis Walshe, F.R.S The morning sessions were devoted to discussions on four major topics while in the afternoons short papers on miscellaneous neurological subjects were presented and discussed

As was fitting in the city of Prof Egas Moniz two of the major discussions were on vascular disorders of the brain. On the first morning Dr Seymour S Ketty (Bethesda, Maryland) described the physiology of the cerebral circulation in vascular diseases of the brain Prof G Schaltenbrand (Würzburg) discussed brain pressure in relation to vascular disease Prof P C P Cloake (Birmingham) the various types of obliterative arteritis which may affect the cerebral arteries, and Dr M *Girard and Prof A. Devic (Lyons) intracranial* vascular malformations excluding aneurysms The second morning was given over to the more surgical aspects of cerebral vascular disease The discussion was opened by Professor Riechert (Freiburg im Breisgau) on the surgical treatment of thromboses; and he was followed by Professor Moniz and Dr Miller Guerra (Lisbon) on the angiographic appearances of intracranial aneurysms and angiomas Prof Norman Dott (Edinburgh) on the surgical treatment of intracranial aneurysms and Prof H Olivecrona (Stockholm) on the surgical treatment of arteriovenous aneurysms and vascular tumours of the brain.

The third major discussion was on the parietal lobes This was opened by Dr Macdonald Critchley (London) he was followed by Prof J Lhermitte (Paris) who gave perhaps the most applauded of all the contributions to the congress, on anosognosia and disturbances of the body image and Prof H Hoff (Vienna) on the coöperation between the right and left parietal lobes; while the fourth contribution by Prof D E Denny Brown (Boston) on parietal lobe apraxia was read in his absence by Dr Merritt

The last morning was occupied by papers on the metabolic diseases of the brain Prof L van Bogaert (Antwerp) and Professor Klenk (Cologne) discussed the semiology pathology and biochemistry of amaurotic idiocy Sir Russell Brain (London) described the neurological complications of Gaucher's disease Dr P Castaigne and Dr François Lhermitte (Paris) involvement of the nervous system in glycogen disease and Prof V Giampalmo (Genoa) the lipoidoses

During the congress there were a number of demonstrations the most interesting of these was a series of radiographs showing the development of cerebral angiography in the hands of Professor Moniz and Prof Almeida Lima. The International League against Epilepsy under the presidency of Dr Critchley held a discussion on temporal lobe epilepsy which was opened by Professor Gastaut, of Marseilles

Following the meetings in Lisbon many members of the congress went to Madrid to honour the memory of Ramon y Cajal in this centenary year of his birth The Cajal Museum with its interesting personal and scientific mementoes was open and a meeting was held at which tributes to Cajal were paid by Professor Ibor (Spain) Prof John Fulton (U S.A) Sir Russell Brain Professor de Wulff (Belgium) Prof. J O Trelles (Peru) and Prof F de Castro representing Cajal's pupils

HÆMATOLOGY

THE 4th congress of the European Society of Hæmatology was held in Amsterdam from Sept 8 to 12 Over 500 members were present as well as about 250 guests In all, at least 28 different countries were represented The main subjects chosen for discussion at the scientific sessions were immuno hæmatology hæmoglobin metabolism and erythropoiesis, acute leukæmia lymph node puncture the blood platelets, and coagulation Although no sensational advances were reported the congress made it very clear that hæmatology is rapidly growing in complexity and in importance as a branch of medicine and pathology In all over 100 papers were presented

There was evidence from several sources that some types of drug induced as well as idiopathic" thrombo cytopenic purpura are due to anti platelet antibodies, and that anti-leucocyte antibodies may similarly be responsible for some types of granulocytopenia Both in-vivo transfusion experiments and in vitro agglutination tests lead to this conclusion

The relation between porphobilinogen (excreted in large amounts in cases of porphyria) and the porphyrins was outlined by Prof C **Rimington** (London), it is becoming clear on both clinical and experimental grounds that barbiturates may be a potent cause of porphyrinuria Dr J **Waldenström** (Malmö) referred to a large family in North Sweden of which 150 members were known to have suffered from congenital porphyria

In the discussions on blood coagulation, the main centre of interest was the mechanism of generation of blood-thromboplastin Dr F **Koller** (Zürich) presented evidence for the existence of yet another coagulation factor ("factor 10"), and Dr N **Rosenthal** (New York) described a third variety of hæmophilia Unfortunately there seemed to be no promising therapeutic advances

Dr R G **Macfarlane** (Oxford) presented a film of marrow puncture which was particularly well received, being both educational and amusing A notable demonstration was the projection by television on to a very large screen of a series of demonstrations given in a nearby building The definition was extremely good and the demonstrations could be seen in comfort by an audience of a hundred or more

The president of the Dutch Hæmatological Society, Dr S I **de Vries**, the secretary-treasurer, Dr M C **Verloop**, and the remaining members of the organising committee deserve great credit for the organisation of this successful congress

---

Points of View

PERIODIC MEDICAL OVERHAUL

Sir Adolphe Abrahams
O B E, M D Camb F R C P
CONSULTING PHYSICIAN, WESTMINSTER HOSPITAL, LONDON

Mr A B was sent to me with a tumour in the right hypochondrium so large that he himself had become aware of its presence He was a prominent executive in a large American industrial company, so valuable an employé that it was highly desirable to ensure so far as possible his immunity from illness Accordingly he had been investigated by a clinic in Detroit, and when I say investigated, nobody who has had any acquaintance with transatlantic thoroughness will need any reminder of its nature and scope For after all, what was a few dollars', or for that matter a few hundred dollars', expenditure on insurance by a wealthy company? He had been given a completely negative report only three months previously Now here was he with a retroperitoneal sarcoma, and six weeks later he was dead.

Dr C D came to me because he knew of my interest in athletics, and, proud of his physique at the age of 50, wished to exhibit himself as a remarkable specimen for his age More to please him than to entertain myself, I went through the orthodox examinations, including of course the urine To my amazement, this exhibited Bence Jones albumose I referred him at once to the experts who deal with this rare anomaly, and they confirmed my observation Dr C D succumbed to multiple myelomatosis before his 51st birthday

Sir E F consulted me for "indigestion," by which he meant vague abdominal discomfort and nausea The duration of his symptoms was three weeks, hitherto his health had been in all respects satisfactory No time was lost in appropriate investigations and within 7 days he was on the operating table Carcinoma of the stomach with widespread dissemination was revealed Presumably his lesion started *at least 6 months in advance of any symptoms*

* * *

Articles, lectures, and broadcast invocations reiterate the advantage and value of a periodic medical examination *when well* In this way, it is represented, future illness may be avoided or early evidence of trouble already present discovered and arrested Comparison is made with the routine overhaul of a motor-car—a specious but, I think, a spurious analogy To indulge in a comparison at least no less applicable, nobody, so far as I am aware, advocates regular precautionary visits to our legal advisers with the idea of protecting ourselves from misfortunes and conflicts with authority We think it more reasonable to wait until trouble arises and then to ask them to get us out of the mess

EXAMINATION

But accepting the principle, what would be the minimum examination and investigation to constitute a net fine enough to catch essentials yet coarse enough to be practicable?

Taking the temperature Examination of the cardiovascular system and the lungs Palpation of the abdomen Testing the pupil reactions and the tendon jerks Estimation of hæmoglobin, a red cell count, a total and differential leucocyte-count Testing the urine for albumin and sugar Radiography of the chest Ophthalmoscopy Sigmoidoscopy might even be included Precautionary measures might be extended to a barium meal, a barium *enema, and intravenous* pyelography, to an electrocardiogram The blood to be examined for a Wassermann reaction and for estimation of non protein nitrogen Gastric analysis, especially for achlorhydria There is literally no limit to the number of possible excursions into biochemistry

What might we reasonably expect from such a procedure? Certain superficial discoveries a lump in the breast, a polyp of the large intestine, a pigmented mole, and other potential candidates for malignancy Reassurance—admittedly on occasion with precocious confidence—is another asset Here and there entirely unexpected revelations will occur But as I have suggested, and as any practitioner will agree, only too often the most elaborate investigation fails to discover a mortal disease even in a comparatively advanced stage Against these sometimes uncertain advantages must be set the expenditure of time and money and the danger of creating hypochondriasis and what may be called disease mindedness

INTERROGATION

An alternative method of investigation is to refrain altogether from physical examination and rely upon an elaborate interrogation These are the sort of questions recommended

Have you any tightness in the chest on exercising?
Any cough? (Not forgetting, one hopes, to inquire about cigarettes)
Has there been any change in your appetite of recent date? Any soreness of the tongue?
Have you at any time seen double? Any queer sensations in your limbs?
Do you feel better in cold or hot weather?
Any bleeding from the back passage? In the case of a woman, any bleeding after coitus or since the menopause?
Have you noticed any difference in your weight?
Do you take any drugs? (Certain drugs mask symptoms or produce skin disorders or blood diseases)

It is difficult enough, and calls for considerable experience, to assess the significance of volunteered symptoms By this method the doctor would have the additional difficulty of estimating to what extent the answer is what the interrogatee believes to be genuine and what he supposes the interrogator desires

EDUCATION

It should not be forgotten that it is the well, the healthy, who, it is advised, are to be examined According to the dictionary, health is soundness of the body spiritual mental and physical well being It has been said that the conditions for health are:

- Satisfactory environment.
- Freedom from infection.
- Adequate nutrition.
- Congenial employment
- Opportunity for self-expression.
- Sufficient rest and leisure
- Realisation of a goal in life
- A satisfying home circle
- A degree of physical and mental fitness equal to possible stress.
- Ability to adapt to change

It is worth asking if it is not wrong to place the emphasis on the possibility of disease instead of on health mindedness Whatever the mechanism the will to be well is a powerful influence and an encouraging atmosphere should be created But if health routine has to be taught are doctors the best teachers? Preoccupation with disease, necessarily the heritage of our training may not provide the best milieu for health mindedness It may after all be preferable for us to come into line with our sister profession and adhere to our proper métier—the treatment of disease

Personal Papers

HOW DO I TREAT MY DOCTOR?

M A. SIEGHART
LL B

Much has been said taught, and written about the human approach of the doctor to his patient All agree that his success depends largely on the personal relationship which is established but opinions differ when it comes to deciding how this relationship should be formed—whether the principal part should be played by human kindness or perhaps by psychic intuition The truth is, I believe that the question "how do I treat my patient?" will never fully be answered until it has been countered by the far more important one 'how do I treat my doctor?'

Even the most experienced doctor requires an experienced patient one, that is to say who has studied the relationship of doctor and patient from the patient's point of view For his diagnosis the doctor must rely largely on the case-history provided by the patient. Training and practice is needed before a patient can furnish a serviceable medical history

* * *

The first data given in a case-history are usually name address, and age, and if the patient is a woman the profession of her husband For women two important points already arise First as to her age If at all possible an experienced patient will avoid giving an age between 40 and 60 for it is part of the acknowledged armoury of modern medicine to hold the climacteric responsible for all complaints arising in this period of a woman's life. The absence of specific symptoms is immaterial for the concepts of "preclimacteric" and 'post climacteric' cover precisely this contingency Every complaint from toothache to corns may be explained by ovarian deficiency and thus held to be merely functional—a consideration which delights the doctor but has never yet cured a patient.

Quite as important as the question of age is that of marital state No experienced patient will admit to being unhappily married or far worse divorced for she well knows the automatic train of thought such an admission will set in motion: a divorced woman is a misunderstood woman a misunderstood woman is an unsatisfied woman; a woman who cannot lead a full sex life will clearly suffer damage in body and soul. This chain of reasoning cannot be broken—not even by an assurance that one is leading the life of a wanton

The next point raised is the patient's family history and her (or his) constitution This leads to a thorough analysis of the lives and deaths of her ancestors Here the patient who has successfully circumnavigated the Scylla of the "functional disorder" is drawn into the Charybdis of the 'constitutional factor' The practised patient will maintain great reserve in replying to these questions: the hard boiled one will describe herself wherever possible as a foundling

Questions on birth trauma and teething can be evaded by the contention that there is no one alive who can supply this information Of the diseases of childhood the experienced patient will admit only to german measles, and that at a safely early age

* * *

If the skill of the shrewd patient has so far succeeded in depriving the doctor of the possibility of an untimely diagnosis she now has to face a far more difficult task The foundling who has successfully weathered birth trauma teething and german measles, and who is living in a state of psychic equilibrium, in the short period which separates puberty from the climacteric must indicate the symptoms that have led her to the consulting room At no point does the antithesis between doctor and patient become more evident. For the patient, the disease consists of the discomforts which she experiences in her own body To the doctor these are important only in so far as they support his diagnosis. He regards them as symptoms if he can use them and as hallucinations if they hinder him If the patient offers him nothing useful he will try to get what he needs by leading questions, and every practised patient knows how difficult it is to defend her disease against such attempts at substitution

It is still more difficult of course to decide how much the doctor should be told and even more important, in what form If the patient complains too little she is in danger of having her illness underestimated for the doctor regularly deducts at least a half from the "subjectively coloured" report of the patient as being 'one-sided' If she complains too much, on the other hand she risks a diagnosis of hysteria, hypochondria psychic disturbance, or the like—a diagnosis as fatal to the patient as it is tempting for the doctor Where the science of the human body ends, that of the soul begins. It is difficult to report a diagnosis of hysteria, for no X ray can penetrate the psyche, and even necropsy (apart from its other disadvantages) may fail to vindicate the unjustly accused

* * *

Only the patient who circumvents this last obstacle has mastered the difficult and necessary art of correctly treating her doctor and deserves the honourable appellation of 'experienced patient.' She has recognised that the doctor contrary to the layman's belief, is not omniscient but on the contrary has at his disposal only a few well tried diagnoses. The doctor's work thus consists entirely in attempting to classify his patients under these heads. It is then the patient's difficult and responsible task to provide the clues that will guide the doctor to the right diagnosis. If the attempt fails, it must be repeated again and again but each time with a different doctor for there is nothing more hopeless than to try to change the mind of a doctor who has once reached a diagnosis.

Whoever can grasp this pattern of things and fashion her behaviour accordingly is the experienced patient struggling optimistically for health But she must recognise that she cannot demand a cure as of right. A cure can result only from the fortuitous encounter of a disease with a doctor embodying the correct diag nosis, and is thus an incredible fluke Only if she has this remarkable luck does the experienced patient become the satisfied patient, the patient *par excellence* whose medical creed runs

> " Easy it is of medicine the sense to comprehend
> " You analyse the worlds both small and large,
> " To leave it safely in the end
> " In Heaven's charge "

JUVENILE DELINQUENCY IN NORTH AMERICA

A NEW comparative survey[1] shows that, in the management of juvenile delinquency, the similarities between Canada, the United States of America, and Great Britain, are far greater than the main differences In Great Britain more attention is paid to due legal process, while in the U S A the philosophy of social work has exercised a powerful influence—the child's need being the paramount consideration In Canada much is owed to British concepts of legal process, but there has been a greater receptiveness to modern sociological and psychological ideas

Professor Tappan, who has made the survey, is impressed by " the widening gap between the basic philosophy of justice that has characterised court behaviour generally (in the U S A) and that which is evolving in children's courts " , and he expresses concern that courts have had virtually no attention in recent years from the legal profession and very little more from social scientists and other relevant specialists In Britain, too, lawyers as a body have neither contributed much to the evolution of an appropriate technique of administering juvenile courts, nor regarded sympathetically the efforts of others to do so

YOUNG OFFENDERS

Diversity of practice in the U S A extends throughout the field of delinquency Upper limits of juvenile court jurisdiction vary from the age of 16 to 21 years, and there is greater overlap than in Britain, between these courts and the jurisdiction of adult criminal courts Only in some 50 of the 3000 counties of the States have strictly specialised juvenile courts been established , in the mixed courts of the remaining counties the judges, without special training or experience, tend to carry over into work with juveniles the ideas and methods of adult courts Criminal courts still deal with some 20% of all children's cases—whereas in Britain today it is rare for a juvenile case to be heard in a criminal court

Professor Tappan complains that, where they exist, juvenile courts in the U S.A tend to " skirt the issue of guilt," and that there are organised efforts to convert the court into something like a general welfare agency Upwards of half the cases are dealt with informally—i e , without a charge being preferred Social investigations are made before the verdict, and often the investigation of the charge is merely perfunctory , the welfare-minded American public accept this without comment, though the practice may threaten the children's legal rights The public do not realise that the courts' capacity for providing treatment is gravely inadequate Our own magistrates are no more trained or experienced than the American ones, and a parallel can be drawn with the probation system, which, though it was introduced in 1896, is still handicapped by the poor quality of the training of its officers Professor Tappan comments " Professional social work has continued to be somewh naive about the rôle and the inherent limitations probation in a juvenile court " He makes a strong ple for cooperation between courts and child guidance clin —neither agency, he says, can function with comple effectiveness without the participation of the other

American disposal and treatment of juvenile offende are closely parallel to British , however, we learn th New York is a fair illustration of " the slow evolut towards the goals of children's court performance Even up to 1945, some children in New York we detained in jail because of lack of detention accomm dation, and in other parts of America, in 1953, this i still a commonplace Even London, that despair o social workers, is not so badly placed as that Th some juvenile court judges act on the theory that in custody is a legitimate method of correctional " shoc treatment " makes familiar reading , but the notion i spreading that to do any good detention must meet th child's mental and emotional needs and contribut towards his understanding of his position

The American penal system " outgrew," as the rep states, the use of corporal punishment by the courts the early 18th century, and the American people can congratulated on having none of the second thought the lingering longing to hit somebody—that have been much in evidence in Britain lately The list of punis ments used in detention institutions, however, mak rather gruesome reading, and includes, in some pla and to a slight degree, corporal punishment Perha 10% of delinquents are committed to institutio roughly comparable in range to approved schools borstal institutions together, and administered eith by the State or by sectarian or philanthropic as they are here These institutions, like ours, handicapped by difficulties in getting staff of calibre It follows that the training given is below standard reached in the American public schools, trade training does not get trade union recognition

British public opinion is widely convinced that battle of the Old Bailey can be won, like Waterloo, the playing fields. Professor Tappan notes this idea al in the U S A " There has been an unusual amount faith, however naïvely it, is inspired, in the value competitive athletic activities and callisthenics in development of character and self discipline " other method of treatment is used anything like so fre The ratio of psychiatrists working in State institutio to the delinquent population is only about 1 325, the complement of psychologists and social worke though rather higher in Canada, is likewise hopeles inadequate On neither side of the Atlantic has a serio attempt yet been made to develop a technique psychiatric treatment in delinquency institutions though wild and unjustified statements are made about the influence of psychiatrists in this field

PREVENTION

An indeterminate sentence is commonly used America, and makes possible a policy of release, depen ing on the adjustment of the individual Neither Br nor in the U S A is aftercare and follow-up sufficiently seriously or at a proper professional leve and the field of prevention of delinquency presents chaotic appearance Edwin J Lucas wrote in National Probation Association Yearbook, 1946

> " Perhaps the fault lies in the multitude of theories a these days concerning crime causation. Each so-cal ' preventive enterprise ' has its own concept of causation which it adheres with a tenacity which would evoke admiration if the concept were more valid Thus it has be said that crime is due to the following empty churc broken homes, poverty, parental neglect, cheap commercial recreation or not enough recreation, comics, mystery sto

---

[1] Comparative Survey on Juvenile Delinquency Part 1 North America The first of a series of five regional reports planned by the United Nations Department of Social Affairs Division of Social Welfare By Dr PAUL W TAPPAN professor of [illegible]logy and lecturer in law at New York University

dio thrillers sex stimulating movies, excessive mobility of opulation illiteracy malnutrition, glandular imbalance eble-mindedness bad eyesight and infected teeth

' In pursuance of those beliefs there have been myriad hemes: the prohibition of intoxicating drinks, of coffee f some soft drinks of tobacco of juke box machines the ontrol of movies and radio the abolition of comics and elieve it or not the installation of more electric lights on reet corners. It has been proposed that parents be prose-uted and sent to prison. In San Francisco parents have been sentenced to parental schools to learn how not to ontribute to the delinquency of their children And in New ersey parents are being invited to attend classrooms with eir children.

We have also had ' boys and girls weeks and someone ecently offered a large sum of money to finance an annual crime prevention week ' Judges have placed children on robation on condition that they read certain prescribed terature and it has been proposed that piano playing is an ntidote to antisocial behaviour Meanwhile newspaper ditors district attorneys and police commissioners are onvinced that the only genuine crime preventive is the ertainty and severity of punishment, swift and punitive ustice Legislation has been passed to require the sterilisation f hopeless idiots and imbeciles and to limit immigration on e theory that the foreign born are more criminalistic than e native born.

A well known national magazine with an enormous rculation for some years has had a monthly feature devoted o techniques of crime prevention. Of the fifty two nportant men who in as many months contributed articles n the subject one was an ex president of the United States o were mayors seven were law-enforcement officials, ineteen were congressmen one was a rear admiral, sixteen ere governors five were prison wardens, and one was the dge of a civil court. There were no criminologists, sociolo ists, or psychiatrists among them

From all of the foregoing it appears that there is no end to e proposals for prevention, because there is as yet no clarity f thinking on the genesis of the phenomenon we are trying o prevent. The clarity of thinking we hope for may be npossible to achieve until behaviour scientists have licited greater exactness from the veritable mountain of onfused and confusing material accumulated each passing ecade

In Britain, too everyone thinks it legitimate to have a o at the subject of causation of crime, but any proposal o study seriously and in depth its psychological back round produces more public anxiety than support f only all speakers at political, religious, or social elfare conferences on crime could be invited to read nd helped to understand, the implications of the above uoted extract, perhaps their speeches would be shorter nd their thinking clearer

There are two interesting developments in preventive ork first the emergence, notably in New Jersey of ommunity Coördination Councils—panels of responsible ocal citizens who deal with all the delinquency problems hat can be handled outside the criminal court With olice coöperation and the support of an informed and able local public opinion this idea, competently under aken has much to commend it Secondly a Federal ct of 1040 authorises the establishment of Youth orrection Authorities—small boards of professionally ualified members with wide responsibilities for organising tate run preventive and correctional activities Being ne stage removed from judicial cares, they are in a etter position to take a wide view of the problems volved

Orthodox sociological research has revealed the ommon ecological patterning of delinquency and of ocial disorganisation in the larger cities. Social reformers ave hoped that an increased saturation of assorted elfare services in bad areas may do the trick Recently, owever, the British public too has begun to doubt hether the difficulties do not run deeper and lie in faulty elationships within the family of the delinquent. merican public opinion is nervous lest counter action might imply some inroad being made into individual freedom and some chiselling of the bases of the social order

A modern psychiatric view holds that the main hope for the prevention of delinquency and the establishment of positive mental health is in greater understanding both of intrapsychic conflict and the nature of disturbances in relationship of an individual with his family his community his ethos and his faith To gain this understanding needs deadly serious exact scientific study and to apply it successfully to delinquency requires that the legal instruments used shall be made capable of working with human nature

MEDICAL DEFENCE UNION

At the annual meeting of the Medical Defence Union on Sept 15 Dr S Cochrane Shanks the president referred to the rising tide of litigation There are, he said several causes Perhaps the most potent is that the hospitals are now State institutions, and so are fair game In the past a patient might hesitate to sue a voluntary hospital or a doctor who gave his services free Not so today; for it is the Treasury which pays, and the doctor too now that he is salaried Another powerful encouragement to the discontented patient is the Legal Aid and Advice Act of 1949 under which litigants may receive free legal assistance in their actions against hospitals and doctors

> In this welfare social estate of ours a patient may be provided with free medical treatment by the State and may subsequently at the State's expense sue the State for negligence. He will if successful in his action, receive compensation from the State He will even if unsuccessful have his legal expenses paid by the State and, being a poor person under the Act will not be called upon to pay the legal expenses incurred by the State in rebutting his unsuccessful and sometimes frivolous suit Was even Dr Faustus submitted to greater temptation ?"

Two other factors, Dr Cochrane Shanks continued, add impetus to this flood The first is the example of the compensation paid to injured persons under the Road Traffic Act. In road traffic accidents the doctrine of *res ipsa loquitur* reigns supreme and there is in the minds of the public—and sometimes even in that of the courts—an unfortunate splash-over into medico legal cases. I have not been cured I must therefore receive compensation is becoming almost a slogan

Finally there is the attitude of the less intelligent public press Negligence real or alleged on the part of the doctor is news—maybe headline news. By the time the negligence has been disproved to the court's satisfaction the story is dead and other sensations have taken its place But the impression left with the litigious patient is obvious

The Union's council, through its representatives has continued joint negotiations with the Ministry with the object of defending unwarranted actions together and of settling just claims by a defendant in amicable agreement Dr Cochrane Shanks said that he has every hope that agreement may soon be reached between the three defence societies the British Medical Association and the Ministry

The Union's annual report shows that in the year 1952 the number of cases passed to the solicitors rose from 182 to 228 The issue of professional negligence arose in 05 cases 7 were concerned with the defence of members or the prosecution of non members before the General Medical Council 3 with unqualified practice 23 with libel and slander 42 with inquests and 26 with representation of members before one or other of the disciplinary bodies under the National Health Service In 15 instances members sought help in difficulties arising out of appointments held by them

In England Now

A Running Commentary by Peripatetic Correspondents

It was too wet to harvest, so the farmer decided to drench his sheep and lambs as a prophylactic against worms in general and liver-fluke in particular I acted as nurse, pouring out 10 ml doses into a graduated bottle while he forced the medicine—carbon tetrachloride, suitably flavoured—down their throats We watched anxiously for any of the reactions mentioned in the warning note on the tin After 48 hours, just when we thought all was well, one lamb began to stagger around in small circles, finally collapsing motionless The flock was quickly assembled with the aid of a capable sheepdog, and several of them were found to have greatly swollen ears and to be drowsy When the vet arrived he gave them all a shot of an anti-histamine compound, issued a very poor prognosis for the bad one, whom I christened Alice, and hoped none of the swollen ears would become gangrenous and fall off On our night-round all was well, but it was an anxious group that peered into the barn the next morning To our relief Alice was much better and there were no gangrenous ears—these had on the contrary all subsided On being let out to graze, however, Alice proceeded ceaselessly to beat the bounds of the field, nor did she ever stop to graze After some hours of circumambulation we put her back in the barn, where she lay motionless in the darkest corner and had to be fed on slops But when I left at the end of my holiday, Alice, after three anxious days of careful nursing, was at last beginning to perk up

The vet told us that contributory factors to the reaction were the wet weather, a recent change of diet from rough grazing to rich meadow pasture, and drenching too soon after dipping He pointed out that only lambs had been affected, and then only white-eared lambs, the pigment in black-eared lambs protecting them from the action of actinic rays Illness, it seems, is no less complicated in sheep than in humans, the dangers of drugs no less great, and after all there are hidden virtues in the black sheep of the flock

* * *

Sex and politics are the life-blood of journalism, though some papers have yet to hear of politics Slumming in the back-streets of the human marrow, the intelligent observer cannot help noting from the columns of the *Daily Blast*, the *Reticulosight*, *Kupffer's Weekly*, and the *Myeloid Courier* the interest of the average marrow inhabitant in political affairs For those who would like to dip into these periodicals a short vocabulary of politico-hæmatological terms is appended

Clot retraction	M P explaining a faux pas to the House
Shift to left	man who takes out a subscription to the *New Statesman and Nation*
Shift to right	man who cancels his subscription to *N S & N*
Red cell	shop steward

Stab cell	assassin
Colour index	depth of political conviction
Standard deviation	angle of banner at Party rally

* * *

Any doctor interested in allergy could not fail to appreciate the report and photographs of a baby walrus with allergic eczema of the face due to milk in its diet Yet, such clinical findings are not unequalled in my own practice, for instance, a young woman with asthma told me that she had two canaries in her home one of whom strangely enough also suffered from asthma A miserable bird, it had been condemned to a life of wheezing dyspnœa by the veterinary surgeon Such a challenge could not go unmet, and my prescription of a 2% ephedrine solution to add to its drinking water produced a remarkable change The bird became lively and cheerful and to the joy of all it began to sing for the first time Three trials were made, with and without the ephedrine, with the same result But pleasure came with it responsibility The young woman still has attacks of asthma and is clearly feather-sensitive Close contact with feather dust is undesirable for her To which patient do I owe the greater ethical responsibility? Perhaps the decision may be made easier by the fact that the young woman cannot sing.

* * *

When I arrived in America some two years ago people said, "You're a Scotsman, aren't you?" A few months later they said, "Which part of England do you come from?" Later still, they asked, "How's Canada these days?" But I was shaken when I penetrated beyond the Mason-Dixon line and found them saying, "Y a Yankee, aren't you? How's Boston?" It will be to return home when I am hailed as a fellow citizen by someone from the East side of Brooklyn

* * *

I count myself fortunate to be a whole-time univ worker, but it means that I live modestly My hom is close to the teaching hospital, so I cannot that a car is anything but a luxury I have sold m and taken to the bicycle which I bought years ago have hardly used until now My preclinical regard me as an intellectual snob who wishes to mistaken for a proper academic worker The clinicians express concern about my health and me to a full measure of their bedside manners. students no longer bother to conceal their contempt somebody who has finally given unequivocal proof having taken the wrong path in our noble profession

But there are advantages in the new a The small amount of extra time I spend on travel is more than offset by not having a car to clean grease at the weekends On a fine Sunday, a cycle ri of twenty or thirty miles en famille gives a view of countryside not easily caught from the driving seat a hurrying car Most of all, it is easier to be an enthusiast motorist if you are not bothered with an actual machi to go wrong For a small weekly subscription y can take the *Motor* or the *Autocar* and indulge y imagination while following current trends in desi and performance One week I scream around in a Jaguar XK 120, another I move with spee distinction in a pre-war V-12 Lagonda, the last creati of the famous W O Bentley, then the stark of an Aston Martin DB 2 makes an irresistible appeal and on wet weekends I become plush-minded and along in a Rolls or Daimler You can see that as armchair motorist I now enjoy not only variety b also a class of car almost entirely reserved in real l for film-stars and gynæcologists

News from the Far East—There are about half a doz frogs jumping about my sitting room, while quite a numb are waiting outside for admission lizards of various s and in considerable numbers, 15–20 at a time, decorate walls and ceiling Useful creatures they are, since they ca troublesome insects, and I pray that there may be more them D D T resistant mosquitoes, and indeed insects every description—such as cockroaches and moths of tr mendous size—offer a paradise for the research biologist am prepared to give hospitality to anyone who wishes undertake studies with a view to getting rid of most of fellow guests I am even willing to serve as a test subj for his investigations as to whether any substance des to kill the smaller world is more harmful or less harmful human beings I can say no more

Letters to the Editor

MODIFIED BOTH RESPIRATOR

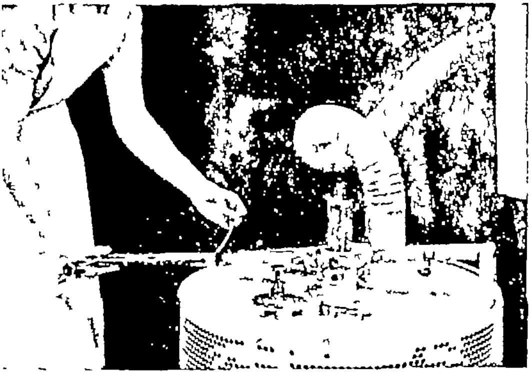
3IR,—The experience gained in modifying the Both pirator[1] and the nursing of patients in the modified pirator showed that more could be done to provide patient with greater comfort and to reduce the rsing difficulties.

ange-over to Manual Pumping

Two disadvantages remained after the pump had been odified. The first was that the change over to manual umping in the event of a failure or a cut in the electricity pply or a motor breakdown was very difficult especially ice if the failure occurred at night, the change-over ight have to be carried out in partial darkness This ight well be beyond a nurse s capabilities. The second sadvantage was that if the switch was left on the storation of the electricity supply might cause serious image to the pump unit, itting it out of action for ours and possibly days he manual pumping was so difficult and could not maintained for any length time without assistance

Dr R W Durand super tendent-in-chief at the ellington Hospital New ealand gave Captain G T nith Clarke chairman of roup 20 hospital manage ent committee details of n improved manual pump ig arrangement The credit r the basic ideas belongs to r Durand and his chief ngineer

Fig 1 shows how a nurse an change over from electric manual pumping with the ew arrangement. The com onent parts for the modified unit are included in the kit to be supplied by the Ministry of Health for the modification of Both respirators The change over consists in removing the gudgeon pin from the central shaft of the pump (a simple operation) removing the T -shaped pumping handle from its holding clips on the top of the pump unit fitting it to the horizontal pumping arm by inserting it into the tubular T ' handle and securing it with a pin attached to the handle (fig 1) Pumping can then be started and instead of having to move the handle vertically up and down as formerly, which necessitated stretching over the pump unit, the nurse can stand on the side and pumping is much easier because of the long arm of the T' handle. If the electricity is restored the pump is worked electrically and the piston going up the shaft can do no harm The nurse can then switch off the electricity for a second, reinsert the gudgeon pin through the hole from which it was removed and the electrical pumping continues when the current is switched on The noise of the pumping is much less with this new improvement



1—The "T" handle is removed from holding clips on top of the pump unit, and hen attached to the horizontal pumping arm which fits into the tubular "T handle. he handle is being secured with a pin attached to it. The hole from which the dgeon pin has been removed to allow the pumping arm to descend can be seen at he top of the shaft. The pin has been placed in the holding clips on top of the unit r safe keeping

Improved Head-board and Neck-seal

The split head board and neck seal previously described[1] was recently used for an adult male patient, and although this was much easier to use than the fixed head piece with the circular neck collar it still had the disadvantage that the upper section of the split head board when open to the full extent limited access to the patient, and the patient could not be placed prone for postural drainage The split head board has therefore been redesigned to allow the top half when opened, to slide upwards and rest on top of the cabinet.

When the bed is withdrawn there is unimpeded access to the patient and the neck is entirely free (figs 2 and 3) Moreover the patient can be placed prone for postural drainage, and a head-support has been introduced which is adjustable upwards and downwards and can be withdrawn from the head of the cabinet to allow for collection of vomit and drainage from the bronchus This has been done by making a recess in the lower half of the headpiece so that the chin is not pushed forward by the head board

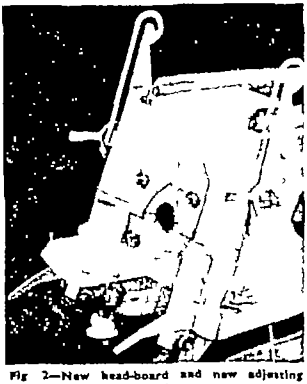


Fig 2—New head-board and new adjusting head-rest.

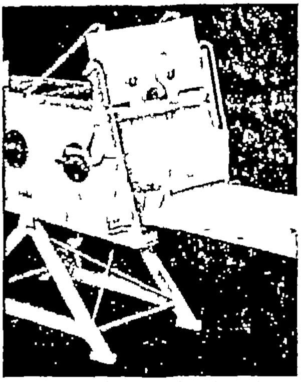

Fig 3—Bed withdrawn showing split head-board in open position.

---

[1] Smith, R. E. *Lancet*, 1953 i 604

All these improvements have been designed by Captain Smith-Clarke, as were the modifications described in my earlier article, reference to which will show the difficulties of manual pumping and of getting access to the patient

Rugby R E SMITH

PREMENSTRUAL TENSION

SIR,—May I comment on your leading article of Sept 12?

In the first place premenstrual tension is not as rare as you suggest, for it was the main source of complaint in 3% of 2000 hospital patients Secondly, your suggestion that progesterone treatment is highly successful is not borne out in my experience, for though it is true that about half the cases are adequately relieved there is little result in the remainder On the contrary, most patients find ethisterone in large doses nauseating, and the common delay in the appearance of the next menstrual period is a source of anxiety to the majority of patients Inhibition of ovulation by androgen therapy during the first fortnight of the period is more uniformly successful, masculinisation is not produced by the small doses used by Bishop In any case this side effect may be completely eliminated by the use of a newer non virilising androgen such as 'Androstolone' This therapy combined with premenstrual ammonium chloride will relieve a great majority of cases

A point of considerable interest from the theoretical point of view is that these patients rarely complain of spasmodic dysmenorrhœa, and their intra uterine pressure during the flow is never high Both these facts substantiate Morton's work on the diminished progestational influence which is probably the cause of the condition

London, W 1 ALBERT DAVIS

MONILIASIS DURING ANTIBIOTIC THERAPY

SIR,—As you stated in your *annotation* of July 25, *Candida albicans* is present in the gastro intestinal tract of most normal people and, being resistant to all common antibiotics, will increase when concomitant bacteria are eliminated by antibiotic therapy

I should like to add that the elimination of bacterial competitors for food-supply is certainly not the only factor involved in this increase of *C albicans*, since it has been reported that some antibiotics have, at least in vitro, a direct or indirect stimulating effect on the growth of *C albicans*

It has been shown by Moore,[1] by Pappenfort and Schnall,[2] and more recently by Huppert et al [3] that aureomycin exerts a direct stimulation on the growth of *C albicans* in Sabouraud's broth, in Sabouraud's agar, and in a semi synthetic broth.

On the other hand, I had observed an indirect effect of penicillin on *C albicans* (1947, unpublished) When cultivated in Schopfer's entirely synthetic medium, this fungus requires biotin as the only essential growth factor When biotin is present in the medium at an optimal concentration, penicillin, even in large amounts, has no effect on the yield of *C albicans* But when biotin is added in insufficient quantity to the synthetic medium, then the presence of penicillin (about 100 units per ml) has a significant enhancing effect on the growth of *C albicans*, as if it acted in synergism with biotin When penicillin is present alone in the medium, without biotin, *C albicans* does not grow at all—a fact which eliminates the possibility of penicillin containing, as an impurity, some growth promoting factor

In the course of antibiotic therapy, elimination of some of the intestinal bacteria necessary for the synthesis of vitamins and other metabolites should have some adverse effect not only on the patient's economy but also on *C albicans* itself, which requires at least one of these metabolites, biotin However, if the phenomenon described above also takes place in vivo, the presence of aureomycin or of penicillin might, at the same time provide a way by which the fungus could overcome this deficiency and proliferate

Evidently, such observations do not yield any information as to whether *C albicans* is actually responsible for the disturbances following antibiotic therapy The abundance of *C albicans* in the stools of patients with sprue or pernicious anæmia may suggest that, in all these cases, some definite change in the metabolic environment in the gastro-intestinal tract is the common cause of the fungus's proliferation

New York City, U S A GEORGES H WERNER

TOBACCO-SMOKING

SIR,—A leisurely investigation into the psychology of tobacco-smoking in average people, which I made over a considerable number of years, leaves me in no doubt that, contrary to what Dr H Pullar Strecker (Sept 12) maintains, tobacco is very much a drug of addiction Precisely the same fundamental psychic attitudes shown by, for example, the morphine addict to morphine are also, on close scrutiny, plainly demonstrable to a greater or lesser extent in the addict to *tobacco Certain things, however, tend to* obscure the kinship between these two addictions

The chief thing is that the textbook picture of the (for example, morphine, opium, hashish) addict, while true of addicts who have fallen into medical hands, is not a correct picture of addicts taken en masse For instance, from conversations I have had with people who have been in the East and who have had opportunities of paying particular attention to the subject it is evident that the vast majority of addicts are not miserable, depraved creatures whose one and only thought is to get hold of their daily supply nor, again, do they require increasing doses to secure the effect of the drug On the contrary, they are average, everyday people who go successfully about their everyday affairs—just like tobacco addicts in this country, provided they are assured of their 10–15 cigarettes a day

However, take away the supply of the tobacco addict and a very different picture presents itself—e g, the child who will *steal and then sell a typewriter* to get money to buy cigarettes Equivalent reactions are revealed by many adults who will spend more annually on cigarettes than would supply a much needed annual holiday, a stair carpet, or an educational endowment policy for their children's education This point can be made still more plainly by considering how, in 1952 the people of this country spent far more on tobacco (£823 million) than on the National Health Service The amount we spend on tobacco and alcoholic drink is almost a quarter of what we spend on foodstuffs Surely such figures betoken "an overpowering desire or need (compulsion) to continue taking the drug and to obtain it by any means," and justify us in concluding that the W H O distinction between drugs liable to produce addiction and habit forming drugs is "hairsplitting"

The definition to which Dr Pullar Strecker refers is unsatisfactory in that it mixes up psychological, moralistic, and social aspects, thereby unnecessarily confusing the issue I would suggest, instead, the following tentative definition of an addiction

> A psychiatric abnormality the psycho economics of which is to effect a psychic equilibrium by means of repeated dependent behaviour directed towards an external and usually inanimate object which is eventually incorporated in the body which develops tolerance to the physical effects of the incorporation on the basic psychic relations with that object being at an oral level of libidinal development and the dependence being such that equally satisfying substitute relations with *other objects cannot be established* with, consequently, the production of withdrawal ar

---

[1] Moore, M. *J Lab clin Med* 1951 37, 703

[2] Pappenfort, R B Schnall E S *Arch intern Med* 1951 88 720

[3] Huppert, M., MacPherson D A., Cazin J *J Bact* 1953, 65 171

mpted substitute symptoms when the physical source of gratification is removed.

uch a definition holds even in those cases where drug is taken by injection; for in addition to the ariable oral psychic symptoms revealed on investiga 1 other psychiatric symptoms deriving from other els of libidinal development also enter into an liction and may superficially obscure the basic iical picture Such a definition also would not only 'er the 'malignant addictions, as Glover calls m but also include very interesting 'benign' lictions not mentioned in textbooks. These include 'essive milk drinking in adults (the least complicated m of addiction) and barley-chewing and turnip wing cases of which have been referred to me by ctitioners because of the chronic, compulsive, absorb , and inordinate extent of such activities

OCCUPATIONAL HEALTH SERVICE

IR,—Dr Parker, in his letter last week recognises danger of setting up a separate occupational health iical service with all the duplication and waste which t would entail So far in this country we have only ched the fringe of occupational health In the coming ırs we shall see a growing realisation that the health a man or woman must be considered in relation to his her total environment, this need applies as strongly shops offices shipyards, and farms as it does to tories An occupational health service is necessary in ler to increase both the health and the wealth of the mmunity

Such a service, however well organised at the top anot become a reality until the family doctor is enabled consider the patient in relation to all the circumstances his life. The present contribution which the 18,000 itish doctors make to occupational health is equivalent the employment of not more than 200 whole time ctors, if as many The 10% of G P.s who play some all part in industrial work must be raised to 70% or re. This can be done only if there is an efficient gional organisation for occupational health to which e G.P can look for advice and training

The Medical Practitioners Union recently published memorandum on this subject The most important nclusion reached was that an occupational health rvice must become an integral part of the National *ealth Service and not merely be coördinated with it.* is could be well achieved by transferring the Factory partment to the Ministry of Health thus keeping the perience of the Factory Department and ensuring its tegration with the other health services

The organisation of an occupational health service at gional level raises a more controversial issue Various asons (which I have no space to give) impelled us to e conclusion that the local health authority (county county borough) was the only practicable body for e purpose Each M O H would then have an additional sistant M O H in charge of occupational health The nction of the latter would be to train advise, and tegrate the work of the G.P.s in the area in so far as cupational health was concerned In the larger areas veral whole time doctors would be needed; communal udies on morbidity would be undertaken and research rk initiated

Only with some such regional organisation will G P.s enabled to play a full part in occupational health rk. No cadre of experts can replace them When I pressed this view to the T U C conference recently I s asked whether the G.P was going to learn occupa nal health at the expense of the patient. The speaker d not appreciate that sound clinical knowledge is the sis of occupational health work and that no theoretical aining can possibly fit a doctor to enter any kind of factory and deal with all its problems He *must* learn on the job

I hope that the medical profession will insist that a unified health service is the only one capable of producing true occupational health

PHENYLBUTAZONE

Sir,—During the course of an investigation into the correlation of therapeutic effects with blood levels in phenylbutazone therapy we have noticed in recent months a diminution in the clinical response with a corresponding fall in the serum phenylbutazone levels, sometimes to blank values on a dose of 600 mg daily We have reason to believe this is due to a change in the coating of the tablet with consequent reduction of absorption of the drug It has been possible by splitting the tablet before ingestion to obtain therapeutic effects and serum concentrations similar to those previously obtained, without any increase in the incidence of gastric disturbance

MALARIA IN SERVICEMEN

Sir —A number of cases of malaria have been found in Servicemen who have returned from abroad [1 2] Last year at the Military Hospital, Tidworth [3] we saw 102 cases which were diagnosed by finding *Plasmodium vivax* in the blood

Of these 102 patients, 69 were having a first attack (suppressed primary cases), and 33 had had one or more previous attacks All these patients had returned from service in Korea, Malaya, or Hong Kong While stationed overseas all patients had been on suppressive proguanil ('Paludrine') 100 mg daily which was stopped some time during the voyage home The distribution of cases was as follows

From	*Suppressed primary cases*	*Relapsed cases*	*Totals*
Korea	46	20	66
Malaya	9	13	22
Hong Kong	14	0	14
Totals	69	33	102

Clinically the patients presented with fever sometimes with a *rigor* and some with *general malaise headache* anorexia, and upper respiratory symptoms Only 34 had palpable spleens All patients responded rapidly to treatment with quinine gr 10 and pamaquin 10 mg thrice daily for 14 days Bed rest was enforced during treatment, and no serious toxic effects were noted A follow up of these cases 6 months to a year after treatment revealed 6 proven cases of relapse, and 4 in which there had been undiagnosed short-term fevers 4 patients could not be traced This accords with the usual relapse rate on such treatment

The possibility of a subclinical parasitæmia preceding clinical manifestations was investigated by blood films taken from 84 fit men of the Gloucestershire Regiment approximately 6 months after proguanil was discontinued There was only 1 *positive* result—in a man who had already had two recent attacks treated with quinine alone. Of the apparently normal men in this group 2 subsequently had attacks, one 4 days after the test and one a month later There thus appeared to be no obvious subclinical parasitæmia

The use of proguanil as a suppressive agent is now well established even though drug resistance arises in some strains of *P vivax* and *P falciparum* The latent period

---

1 Macdonald, G *Lancet* 1952 ii, 45
2 Adams, A R. D., Seaton, D R. *Ibid.*
3. See MacFarlane R. G *Ibid* p 238

between discontinuation of this drug and the onset of clinical disease may be due to drug inhibition or, more likely, to the natural history of the parasite Suppressed primary malaria due to the temperate strain (from Korea) came on after an average latent period of 6 months, compared with an average of $2^1/_2$ months for the tropical (Malayan) strain The distributions of cases in men of the Gloucestershire Regiment (from Korea) and the 4th Hussars (from Malaya) were as follows

				1952				
From	*Feb*	*March*	*April*	*May*	*June*	*July*	*Aug*	*Sept*
Korea *	—	—	2	1	14	6	3	1
Malaya †	3	2	0	3	—	—	—	—

* Embarked Nov 21, 1951
† Embarked Nov 12, 1951

This attack pattern may, however, be explained on a seasonal basis, the temperate zone strain manifesting itself in the summer, and the tropical strain all the year round [4] Investigations into the attack rate in those at risk was not possible, owing to rapid dispersal by demobilisation and transfer to other units

Tidworth, Hants.

WHAT IS ULCERATIVE COLITIS?

Sir,—Mr Brooke, in his letter of Sept 12, refers to a paper by Felson and Greenberg [5] reporting that 10% of 122 patients had developed ulcerative colitis at the end of a year, following an epidemic attack of Flexner dysentery It should be added that in none of these patients had the diarrhœa cleared up since the initial attack Mr Brooke could also have referred to a later paper by Felson and Wolarsky [6] in which they give an account of 61 cases diagnosed as chronic ulcerative colitis in military personnel In 33 of these cases the onset of the diarrhœa could be traced to a definite attack of dysentery and almost all of the patients had had their initial attack where dysentery was either epidemic or endemic

I contend, however, that these patients did not develop "ulcerative colitis" in the generally accepted sense of the term Rather, their colons suffered permanent damage as a result of their attack of dysentery, giving rise to the condition best termed postdysenteric colitis This condition may have some points of similarity to ulcerative colitis and, if the destruction of the mucous membrane of the colon by the attack of dysentery is sufficiently severe, the end-result may sometimes be the pathological state of the colon, far more often seen in ulcerative colitis, described by Mr Brooke in his article [7] One would like to see the case histories of the patients who have had their colons removed by Mr Brooke, after having had bacillary or amœbic dysentery initially, but I suggest that it is possible that they had postdysenteric colitis and not ulcerative colitis, although their colons may have been pathologically similar to those he has removed from patients with the latter disease In the single example which he gives in his paper (case 4), the attack of dysentery may well have been incidental

Mr Brooke's statement that ulcerative colitis follows an attack of bacillary dysentery in a definite proportion of cases is, I maintain, based on a confusion of terminology and is not a valid argument in support of his view that ulcerative colitis is not a specific disease Let us all agree on what we mean by the term "ulcerative colitis," and if some wish to include postdysenteric colitis under this heading, let us add the prefix "idiopathic" to that great majority of cases in which the disease arises out of the blue I have already stated (July 4) some of the reasons for the belief that "idiopathic" ulcerative colitis is a disease sui generis, as Hardy put it (July 11), and I was very glad to that he, with his exceptional experience of the took so wholeheartedly this view

Worksop, Notts J M Rice Oxley

TUBERCULOSIS IN GLASGOW

Sir,—The correspondence under this heading into a general discussion on the control of tub and for this reason I may perhaps be permitted participate despite the long delay I should like support the views of Dr James,[1] who stated that was no evidence that "good housing and a good sta of living will eradicate the disease" and oppose the of Dr Paul [2] who stated that "the tubercle bacillus ubiquitous, and it is ridiculous to suggest that disease can be conquered by physical eradication of organism itself History does not give any instance the eradication of any such epidemic disease in this way

I pointed out some time ago [3] that in 1863 Budd, one of the pioneer epidemiologists, advised medical colleagues to study natural epidemics in anim in order to throw light on human epidemics the first decade of the 19th century there were pe who believed that tuberculosis in cattle could be trolled by raising "healthy" cattle with "sound membranes" that would resist tuberculosis But 1901 M'Fadyean [4] wrote

> "The man whose sense of proportion is not hope defective will attach only minor importance to such siderations, and will concentrate his efforts against the great cause of the disease—the operation of contagion. that has been successfully grappled with predispos becomes of no account "

Work on the control of bovine tuberculosis which been summarised in your columns [5] has shown at least when applied to cattle, M'Fadyean's views essentially sound, and the disease has been eradicated from Finland (where human tub still takes a heavy toll), the vast area of the U S A, the Scandinavian countries Similarly, in Great B a voluntary campaign was begun in 1935 in owners of "attested" tubercle free herds received bonuses Farmers entering the scheme were allowed sell reacting animals on the open market, and purists objected strongly to this, but the reacting were usually from the best herds, with only slight le of tuberculosis, and they entered other herds, nearly of which contained tuberculous cattle the imp thing was that more and more herds were created which there was no tuberculosis, and diseased could no longer infect the young stock Now over 4 of the 9 million cattle in Great Britain [6] are in atte herds and eradication areas have been established which reacting animals will be slaughtered All this been achieved with no dislocation of the milk supply of the trade in cattle in fact it has been achi without the great majority of people (not even, possi Dr Paul) realising that it has occurred This can perhaps be taken as an outstanding example what may be done by the old-fashioned operation enlightened self-interest (even though guided by veterinary profession) and the free play of an " market"

Cattle can obviously be handled much more than men, but there is little doubt that, despite differences, tuberculosis in cattle resembles tubercul in man as closely as any other two diseases and certa as closely as tuberculosis and diphtheria mentioned

[5] Francis J *Lancet*, 1950, 1, 34
[6] *Vet Rec* 1953, 65, 478

James[1] Predisposing factors must doubtless be on much more weight in human than in bovine erculosis but despite the improvement in housing and rition which had taken place by 1947[7] tuberculosis h a mortality of 55 per 100 000 was still the most portant cause of death in Great Britain Even in w Zealand, where living conditions are perhaps better n they are likely to be in Great Britain for some e, tuberculosis, with a mortality of 31 per 100 000 s the highest single cause of death in females 18–35 rs old.[6] Again in Perth Australia 55% of 1069 ldren 10–14 years old were infected with virulent ercle bacilli in 1947[8]

The assumption that living standards, particularly in gland, will continue to rise is perhaps optimistic[9] t in any event better housing and better food depend general economic development, and particularly on activities of builders and farmers There seems to plenty of room for the specific medical and sanitary asures advocated by Dr James[1] and he has already licated what they may achieve[10] one may also int out that human tubercle bacilli have been virtually dicated from the island of Bornholm[8] and there are as in the U S.A[8] where, in contrast to Australia no ool-children are infected with tubercle bacilli In smania, where there has been a vigorous campaign ce 1947 and infected persons are isolated the mortality s dropped from 42 per 100 000 to 11 per 100 000 in first part of 1953 I would submit that we must not ept the ubiquity of the tubercle bacillus it is portant to remember that all people with consumption re once ' healthy reactors,'' and as indicated by Paul[9] *the experience of war shows what will happen* these ' healthy reactors when exposed to adverse nditions.

In their delightful book *The White Plague,*[11] Dr Dubos d his wife pay a courteous tribute to the work that s been done in the control of bovine tuberculosis and rticularly the "skilful policy of segregation' that s been used in Great Britain As they say:

> ' It is by preventive measures that bovine tuberculosis s been practically wiped out in certain parts of the world, d this achievement has had far reaching consequences for control of the human disease. Wherever it has been hieved, the eradication of tuberculosis from cattle has ought about the almost complete disappearance of human fection caused by bacilli of the bovine type It has helped lower the cost of production of meat and dairy products, d has led indirectly thereby to an improvement of human trition and higher resistance to infection Moreover the t that tuberculosis has been eradicated from certain imal populations has fostered the confidence that it could o be eradicated from human populations. '

There was abundant evidence that bovine tuber losis would not have been controlled by any improve ent in the ' standard of living' and Dubos and ubos quote from my book on *Bovine Tuberculosis* hat is perhaps the most striking piece of evidence

> " In 1890 Queen *Victoria ordered* that the dairy cows on e Home Farm at Windsor be tuberculin tested Thirty five the forty cows were found to be tuberculin positive and berculous lesions were found in all of them! And yet he premises on which these cows were kept were probably e best in the kingdom and the general cleanliness left thing to be desired '

In his paper on the ætiology of tuberculosis[12] Robert och wrote:

> ' So much the *more stress* would I therefore lay on prophy tic measures, which should be directed partly towards the direct destruction of the tubercle bacilli by suitable methods of disinfection, partly to the preservation of healthy persons from contact with tubercle bacilli in all cases in which the parasites cannot be certainly destroyed.

These are the methods which have been used to eliminate bovine tubercle bacilli Obviously Koch felt that it was just as important to eliminate tubercle bacilli as it was to destroy *the organisms of cholera or* anthrax The ubiquity of the tubercle bacillus has doubtless been accepted with such complacency for so long[8] because of the difficulty of dealing with the infection now that there are chemotherapeutic agents to aid the treatment of patients and B C G to raise the resistance of exposed groups and so reduce the weight of infection there is increasing evidence that, as with cattle the rational application of hygienic methods will lead to the eventual eradication of tubercle bacilli from large sections of the population

EXTERNAL CEPHALIC VERSION

SIR,—I wish to record an error in my article which I have discovered since its publication on Aug 22

It is stated that in the five year period under discussion there were 67 breech deliveries in 4217 cases—an incidence of 1 35% On re-checking this figure I find it should be 1 59% (The original figure of 1 35% was calculated on the supposition that there had been only 57 breech deliveries, but an additional 10 cases were subsequently discovered and included without a correction being made *to the percentage figure*)

The new figure of 1 59% in no way detracts from the purpose of the article—namely to justify the manœuvre of external cephalic version

If the expected incidence of breech presentation at the onset of labour is something over 3% then our corrected figure of 1 59% still indicates that by version this expected incidence can be approximately halved and *probably more than halved* as was stated in the article

Middlesex Hospital,
London W 1

M R. FELL

ANÆSTHESIA AND CARDIAC DISEASE

SIR,—Your leading article of Sept. 12 is both timely and practical, for it contains an excellent summary of the anæsthetic hazards and, at the same time, debunks some of the out-of-date views about the inevitable safety of local anæsthetic techniques.

All anæsthetists meet physicians who regard generals ' as risky and advocate locals' and even ' spinals in cases in which to the anæsthetist they would be clearly inadvisable. With the increasing knowledge of anæsthetists in spheres well beyond those of ether and chloroform—some actually understanding the significance of such mysteries as the electrocardiogram (and others like myself seeking to do so)—the nature of the help given by the physicians in bad risk cases appears to be changing Surely the opinions of the cardiologists and chest physicians are of the greatest possible value in delineating the nature and extent of the disease, the likelihood of improvement with medical treatment and any particular risk that they foresee with the anæsthetic or operation contemplated It is desirable in such cases for anæsthetists and physicians to confer rather than to leave notes such as under no circumstances should a general' be given ', ' spinal is the anæsthetic of choice here or even as one physician playfully wrote solely for my benefit, balanced anæsthesia would appear to be suitable ! Such advice is not generally sought by anæsthetists, and when given might possibly invoke the reply ' You do it yourself and you explain to the coroner '

Paul, H *Lancet*, 1932 i, 1316
McDougall J B Tuberculosis: A Global Study in Social Pathology Edinburgh 1949

Dubos R. Dubos, J The White Plague: Tuberculosis, Man and Society London, 1953
Koch, R The Etiology of Tuberculosis New Sydenham Society 1886 p 67

No! Anæsthesia has obtained a place as a full specialty and we are at least expected to choose wisely our technique, especially when we are aided by the physicians to a full understanding of the significance of the clinical condition

Lastly, with bigger and better surgery on older and poorer risks it seems necessary to reassert that the surgery as well as the anæsthetic causes some strain even on the heart

London E 11 E K GARDNER

PREVENTION OF POLIOMYELITIS

SIR,—The correspondence on the above subject is of considerable interest, especially to those who, like myself, have to consider how best the public may be protected

I had an outbreak of poliomyelitis in October, 1952, and ascertainment of contacts was proved most valuable by the fact that, with a few exceptions, it was these contacts who either contracted the disease or spread it as healthy carriers The latter point was conclusively proved by the virus being found in the fæces I think it is essential that child contacts should be excluded from school for three weeks, the parents are advised what to look for As regards adults only those engaged in handling children as school teachers or nursery attendants, or in handling food—for example, as waitresses or workers in food premises—need be excluded from work Incidentally if they are *not* excluded the M O H hears about it from the nervous public

The 1950 outbreak of poliomyelitis in the Isle of Wight showed clearly, according to Dr Agerholm (Aug 8), how several cases might have been prevented if adequate control of contacts had been undertaken It is incumbent on M O H s to take all steps possible to protect the public from attack by this disease, and one such step is exclusion of certain contacts

Guildford, Surrey F A BELAM
Medical officer of health

ATTACK ON FLIES

SIR,—I was interested by the annotation on this subject in your issue of Aug 8 While I appreciate your review of the ecology of flies, I think that a most unfortunate impression might be gained from the second part of the article—that regarding the possible over-emphasis on the rôle of flies as vectors of infectious disease

Two important articles[1 2] have demonstrated quite clearly the importance of flies in the transmission of dysenteric diseases These studies show that as a result of effective fly control, both in an area of high morbidity from diarrhœal disease and in one of moderate morbidity, the prevalence of shigella infections, as well as to a lesser extent of salmonella infections, was significantly reduced With cessation of fly control in the treated areas, shigella infections once more rose to almost their previous rate

Although you do not advise relaxation of efforts at fly control, health authorities unaware of this clear demonstration of fly transmission of infectious diseases might, if their funds were limited, decide that fly control could be dispensed with

We here are renewing our efforts at area fly control, and placing the emphasis on basic sanitation to prevent breeding rather than depending exclusively on residual chemical control of the adults

LEGAL RESPONSIBILITY IN BLOOD-TRANSFUSION

SIR,—I have read with interest the article this subject by Dr James (Aug 1) In p noted the list of diseases which preclude an indi from being a blood donor These include asthma, fever, and nettlerash It seems strange that from allergic diseases migraine is omitted

This disabling complaint, said now to affect 6–8% the world's population and to be on the increase, handed down as a Mendelian dominant charac Surely it should not be transmitted indiscriminately transfusion?

London, W 1 NEVIL LEYTO

CONTRACEPTIVE TECHNIQUE

SIR,—The letters from Dr Margaret Hadley J (Aug 15) and Miss Josephine Barnes and Dr Goulding (Aug 22) give an inaccurate impression value of vaginal jelly (especially synthetic gels such 'Preceptin') as a means of contraception It is ce that conclusions on this subject should be based sufficient evidence In support of her opinion Jackson brings forward one case, she is dis because an asthmatic patient became pregnant two months of beginning to use a jelly But I c give Dr Jackson many records of cases on my files which people have become pregnant when using diaphragm and jelly and a sheath

In favour of the use of jelly without a diaphragm may cite the reports of Dr Nichols Eastman[2] of Hopkins Hospital, and Dr Alan Guttmacher,[3] American gynæcologists of high reputation who used this method In observations on 605 couples a period of twelve to thirty-six months Dr Gu found that failures due to the method numbered 0– and failures due to patients' errors numbered 0–1% total pregnancy-rate was 9 1% per 100 woman years exposure In Dr Eastman's series of 333 w observed for six months, the pregnancy rate was 16 per 100 woman-years of exposure The pregnancy when diaphragm and jelly are used together is gen accepted as between 12% and 33% per 100 woman y exposure Stromme and Rothnem,[4] in a survey reports from nearly ten clinics, found that the rate was 4% among women using preceptin compared with 12–15% among women at clinics diaphragm plus jelly, indicating a 95–98% reduction fertility during the reproductive phase

The factors which cause a method to be used re or otherwise are obviously of great importance, Dr Eastman showed that in mass studies the diap and jelly has not proved more effective than alone The ease with which the fertility control can be used may be far more important than kind of efficacy that can be judged in the laborat A suppository or a jelly can be introduced easily requires no fitting, and no repeated visits to a Moreover, Dr Goulding does not mention the uncommon circumstances in which, according to Prof Dickinson, the use of a diaphragm is contra indicated

1 In women seeking premarital advice

2 Where the size of the vagina changes frequently extensively (especially in the first ten years of life)

3 Where the woman is unable to insert or remove diaphragm—either through lack of intelligence or thr lack of facilities

SHUNTING IN THE HUMAN KIDNEY

SIR,—We should like to clarify certain points raised the course of some critical comments in the current dical Annual [6] on our paper in *The Lancet* [7]

The commenter appears to accept our observations, de on some human necropsy material that the renal tex is pale and the medulla congested as demon ated macroscopically and by Pickworth s stain

he takes serious exception to our use of the term hunt' in this connection His contention is that in er to use the term, one must see the blood by passing cortex and flowing through the medulla

n our paper we had set out to collect some "*more ect* anatomical evidence of corticomedullary diversion blood *in man* " than had been forthcoming to date have not claimed that we have demonstrated shunting the human kidneys but, as morbid anatomists who re often to interpret their findings on dead tissues the basis of experimental physiological work we re read our observations as giving evidence of nting It may be relevant to note here that in the *tracts of World Medicine* [8] our observations have n interpreted as adding a valuable contribution support the hypothesis of the Oxford shunt.' We sorry to find that we have failed to give a more ir idea to some readers about what we actually meant could have disregarded the 'static distribution of od [7] after death had it not been that the paren matous damage had also a correlated distribution ch suggests that the former did not merely represent agonal picture—we could have read it simply as tical ischæmia, had it not been that the medulla more congested than normal and that the fatter false vasa recta appeared the more distinct was the tical ischæmia Nor does the reading [7] of con ions from the efferent arterioles of the juxta dullary glomeruli to the vasa recta in control pictures ative our contention. The presence of these cular channels operating normally between the tex and the medulla is universally accepted What have observed is that they become wider under se conditions, and this widening associated with the er features has been interpreted by us as *evidence* gesting the passage before death of more blood from cortex to the medulla than occurs normally—in er words of corticomedullary diversion or of shunting

We feel that the time is not yet ripe for anyone to ak too strongly either in favour of or against this ception which appears to be based on some rational ts and observations Instead one should concen e rather on the collection of further data with an n and unbiased mind

Medicine and the Law

Name Removed from Medical List

A TRIBUNAL constituted under the National Health Service Act has directed that the name of a doctor practising in Cumberland shall be removed from the medical list of Cumberland Executive Council and shall not be included on the lists of other executive councils. This arises from the finding of irregularities in prescribing and dispensing for patients which constitute a breach of the terms of service.

The doctor, who is 31 years of age took over a practice at the end of 1948, and in October 1949 with the consent of the executive council, began to dispense for patients at a subsidiary surgery on the basis of payments according to the Drug Tariff. The offences alleged against this doctor are that (1) he dispensed or submitted to the National Health Service pricing bureau prescriptions in respect of persons (*a*) who were not included in his dispensing list and for whom therefore he had no authority to dispense (*b*) who could not be traced and who are not recorded on his list (*c*) who were deceased at the date of the prescriptions and (*d*) whose names and addresses as entered by him were illegible (2) he submitted for payment prescriptions and also duplicates thereof and where the prescription was for a quantity of drugs or appliances divided the prescription between two or more scripts, or caused it to be so divided instead of including the whole prescription in one script (3) he submitted for payment prescriptions in respect of persons on his list, which he had not actually dispensed to the persons concerned

The tribunal remarks that at least one chemist has suffered very great hardship indeed and serious financial loss through the respondent improperly dispensing his own prescriptions which otherwise this chemist would in all probability have dispensed

The doctor has not appealed against the tribunal's decision and accordingly executive councils have been instructed to give effect to it until the tribunal or the Minister of Health directs otherwise

DEATHS

KAHAN.—On Sept. 16 Nest Kahan (née Thomas), M.B. D.C.H D.P.M

Obituary

ARTHUR RENDLE SHORT

M D , B Sc Lond , F R C S

Professor Rendle Short, whose death we announced last week, was born in Bristol, and he spent almost the whole of his life in that city, where for many years he held the chair of surgery

His father, Mr E Rendle Short, a director of Fry's, the chocolate manufacturers, encouraged the scientific aptitudes which he showed even as a boy at the Bristol Grammar School As a student at the University of Bristol, and at University College, London, he fulfilled his early promise In 1899 he graduated B SC with first-class honours in geology, and in his medical studies he was equally successful, gaining exhibitions and scholarships, and the gold medal in the subjects of materia medica, anatomy, and medicine He took his M.B with first-class honours in 1903 and was awarded a final gold medal when he proceeded to the M.D the following year But he determined to specialise in surgery and after holding resident appointments at Bristol Royal Infirmary, and a lectureship in physiology at the university, he took the F R C.S in 1908 Five years later he was appointed to the staff of the Royal Infirmary, becoming a full surgeon in 1922 In 1932 he succeeded Hey Groves in the chair of surgery On his retirement in 1946 he was made professor emeritus

Rendle Short was an impressive teacher of the old school At the bedside he could quickly sift the essential from a mass of conflicting detail, and signpost clearly for his students the highroads of diagnosis, prognosis, and treatment He could also effectively illustrate the principles of surgery from a particular case, and his dialectical "grinds" (after the manner of a Socrates) in the pathology museum on Monday mornings cleared much clogging debris from the minds of his listeners and taught them how to go to the root of the matter Successive generations of students gratefully recall his continued interest in them One of them writes

"As a teacher Rendle Short was absolutely in the first class he tended perhaps to over-simplify the subject, but what a gift that was to harassed and bewildered students His familiar cliché—'I well remember'—pronounced in an accent which unmistakably told his hearers that he was Bristol and proud of it, became a classic with all his students and residents Some of us felt he deliberately perpetuated this characteristic intonation The term 'a physician who operates' might have been inspired by his practice While he never acquired the extreme manual dexterity of some of the greatest operators, he was a general surgeon in the best sense of the word, and as a diagnostician he yielded place to none

"The guiding principle of his life was his religious faith He never wavered in an unquestioning belief in God and the Bible A forceful, convincing, reasonable speaker who abjured polemics, he sought to carry his hearers with him by consent, and he was in great demand amongst all denominations, especially for young people Students held his first affection, and for them he travelled distances—from Finland to Hungary, from St Andrews to Southampton He used to combine a talk on a surgical subject one afternoon with a religious address in the evening An abrupt manner, almost curt at times, hid a heart which was extremely kind It seems almost incredible that we shall not see Rendle Short again, looking neat and spruce and hardly a day older than twenty years ago"

His medical writings are well known, and each in its turn has made its valuable contribution to his specialty —the *Causation of Appendicitis*, the *Synopsis of Physiology*, the *Index of Prognosis* But perhaps his main service to the profession has been his share exacting and time-demanding editorship of the *Annual* From 1919, first in partnership with the Dr H Carey Coombs, and then with Sir Henry he carried through the immense yearly task of ponding, collecting, and writing up the materi this publication Industry and superb enabled him to put twice the amount of useful into the day that most can manage, and for he also had a large consulting practice and was in d all over the West Country for his diagnostic abilit

W M C writes "Like some of the great science—Newton, Boyle, and Faraday—Rendle S was a deeply religious man and devoted himself ately, actively, and consistently to the Christian He studied recent research in all subjects relevant deeper understanding of the Bible—especially languages of the Bible, its archæology, geology, and general scientific approach To many Christian in the profession and to some who are still students has been the chief barrier to their making an and dangerous divorce between their scientific work the spiritual and moral truths of the Bible He see no necessity for any such rivalry and between true science and true religion, whether problem were looked at theologically, philosoph or scientifically Indeed, he went further From of his own strongly held and practically effective which was grounded upon a spiritual and int conviction that Jesus Christ was alone the Way Truth, and the Life, he has been the means of stabilising the Christian faith of many Ther also not a few who have through him been persua a personal faith in Christ By sheer consistency downright honesty of life, by quiet godliness abounding secret philanthropy, by an intelle clear and wholehearted confession of the Christian Rendle Short has left us a shining example of out in practice what he preached"

Professor Rendle Short died on Sept 14 at Th where he was staying with friends on his way home a conference in North Wales He leaves his wif before their marriage was a sister at the Mildmay Hospital, with a son and two daughters His daughter holds the chair of obstetrics at College in Uganda his son is a pædiatrician at and his younger daughter is a nursing sister in Nair

VALENTINE HERBERT ELLIS

M.A , B Chir Camb , F R C.S

Mr V H Ellis, orthopædic surgeon to St Hospital, London, died on Sept 15 while h finishing his morning's work in the fracture clinic he had himself planned and developed

He was born in India in 1901, the son of General Philip Mackay Ellis, O B.E , A.M.S , and h educated at Wellington and at Clare College, Cam He qualified from St George's Hospital in 1925, became F R C S three years later After hol number of junior appointments at St George's elsewhere he went as surgical registrar to the National Orthopædic Hospital at Stanmore, wh stimulus of such men as Elmslie, Laming Evans, and Trethowan quickly determined his future bent

In 1932, when he was only 30, he was appoint the staff of St Mary's Hospital, and he was the to hold the post of orthopædic surgeon there. tireless energy he set out to establish what has been leading orthopædic and fracture department. He many other senior surgical appointments, chief which were those at the Royal National Ortho Hospital, Paddington Green Children's Hospital, Lord Mayor Treloar Orthopædic Hospital at Alton the Heatherwood Orthopædic Hospital at Ascot the second world war he was in charge of the pædic unit at the E M S Park Prewett Hospital his great capacity for hard and sustained work full expression With a small but highly staff, trained by him, he dealt with an enormous of work, especially from D-day onwards During time there passed through the hospital 16,000 wo of whom many were orthopædic cases. D pressure of routine work, he found time to collect his valuable contributions on the treatment of uries of the cervical spine, the causes of failure in ne-grafting for non union of fractures and early perience in the use of penicillin His later writings luded articles in Platt's *Modern Trends in Orthopædics*, undfield Jones and Porritt's *Essentials of Modern rgery* and Fleming's *Penicillin* He was also a joint thor of *Recent Advances in Orthopædic Surgery* (1937) *He was much in demand for committee work* which undertook ungrudgingly, and he was chairman of the dical staff committee and academic board at the yal National Orthopædic Hospital In 1946 he s president of the section of orthopædics of the Royal iety of Medicine and he had served as honorary asurer of the British Orthopædic Association He s looked on as a likely choice as a future president of association.

T O A. speaks of the great loss to the specialty one of its wisest counsellors Not only was Ellis of the most distinguished orthopædic surgeons of day; he was a scholar with an exceptionally broad kground of knowledge and with interests that ranged m finance to horticulture He will be remembered the qualities which commanded respect from all affection from his colleagues and pupils—his sound mon sense, his wise judgment, his kindly humanity, quiet wit, and his loyalty

W J writes 'Valentine Herbert Ellis, known most of us as Gustav and to some few of his friends Val was quiet and reserved It was not easy to w him well but the more you knew of him the more wanted to know him Once the crust was broken friendship became very strong He was a great ker—perhaps one of the most profound thinkers the orthopædic surgeons of today Every member the select W Little Club, of which he was so long order *will agree with that, and will agree that in these* et after-dinner meetings he made his mark even more n in his important responsibilities at St. Mary's pital and elsewhere What we like to remember he earnest and thoughtful criticism that he could ays make in so friendly a way at friendly meetings.'

With his unfailing cheerfulness good nature and ly interest in affairs Valentine Ellis gave the impres , and, B H B believes, it was a true one, of ng completely happy in his life and work Indifferent naterial gain and to personal ambition he was content to the work he liked conscientiously and well. None less, distinguished appointments and recognition rally came to a man of his worth

He was keenly interested in every aspect of the are of the institutions which he served With his cial detachment and capacity to get to the essence the matter he was an effective member of committees, the number on which he served was exceptional *for these days Ellis was the ideal 'second opinion.'* wide experience careful observation wisdom, and ly helpfulness, made his advice much sought after greatly valued. We shall miss his good humoured endability and his ready and well informed con ation I think his end came as he would have ed, while engaged in the work to which he was happy ive so much of his life

r Ellis married Angela Peart Robinson in 1937 she survives him with a son and a daughter

Appointments

OONE, WILLIAM, F.R.C.S.E.: asst. surgeon, Dunfermline and West Fife Hospital.

QUIBB, J L., M.D. Brist.: asst. pathologist, hospitals in the West Suffolk area.

ELL, J V., M.B. N.U.I D.P.M.: consultant psychiatrist, pswich Mental Hospital group

TON J C. M.D Lond asst. physician, Guy's Hospital, London.

SON L. G M.B. Edin. D.A.: consultant anæsthetist, Edinburgh northern group of hospitals.

E. M., M.D. Birm.: consultant pathologist, Leicester General Hospital

LIFFE, MARY M.B. Camb. D.P.H. asst. county M.O.H., Derbyshire County Council, and M.O.H., borough of Glossop and rban district of New Mills.

TER, G V., M.R.C.S.: appointed factory doctor Alton Staffordshire.

FIELD J M M.R.C.S. appointed factory doctor Chulmleigh Devon.

Notes and News

JOURNAL OF THE R.A.M.C.

THIS journal founded in 1903 by Sir William Taylor has lately celebrated its fiftieth anniversary with a special issue[1] Earlier editors include Sir Robert Firth, Sir David Bruce Sir William Horrocks and Colonel Lyle Cummins. *Of these* Horrocks earns special mention in this festschrift, for he was editor for nearly thirty years; and a biographical note by his son, Sir Brian Horrocks, describes his work in designing mobile water-sterilisers and the box for water testing which bears his name He will also be remembered for his book on the *Bacteriological Examination of Waters* his organisation of hygiene laboratories and his chairmanship of the Anti-gas Committee during the 1914–18 war

Hygiene has always played an important part in military medicine and another paper in this issue, on the growth and development of Army barracks in the United Kingdom reminds us what excellent work military hygienists have done Clinical articles include case reports of carcinoma of the adrenal cortex causing feminism in an adult male of dystrophia myotonica and of Ganser's syndrome A survey of Service psychiatry in the Far East in 1951 the first part of which appears in this issue was written in reply to the comment of a National Service officer that except in bacteriology pathology and hygiene the scope of medicine in the Army was limited.

Nowadays fewer and fewer journals offer material that is of interest to both specialists and general readers, and it is to be hoped that this journal will soon once more be able to offer its varied contents in monthly instead of quarterly issues

CANCER DEFLATED

IN 1946 Dr I Berenblum who has spent most of his life in cancer research, wrote a book for laymen called *Science versus Cancer* which was published in England[2] He has now written a new book, also for laymen based on the former work, and first published in America last year; an English edition has now appeared.[3] In his preface he justly claims that though his approach to his subject is scientific his treatment has been as far as possible non technical. He explains the present stage of cancer research fully and fairly in words which everybody can follow, because as he says, *the ordinary reader still has but a hazy idea of what it is all* about Much of the fear which cancer inspires springs from the belief that it is a complete mystery against which patient and doctor alike are helpless. Some of this fear could be removed, we believe if the general public had a clearer idea of what is already known about cancer and Dr Berenblum rightly supposes that they will be interested to hear how this knowledge was reached. His account will reassure many anxious people because—by giving the known facts, and showing the lines along which research workers are thinking—he thins the mystery His book, in fact, reduces this disease to the level of others which lack its terrifying aura.

This is surely the type of cancer education" which Dr John Burton, medical director of the Central Council for Health Education had in mind when he said, at a meeting of the National Council of Women on Sept. 1 that knowledge is the best antidote to fear His council has suggested a scheme for cancer education, and local authorities are invited to set up small committees, under the guidance of their health departments, to discuss it This scheme is in keeping with Mr Malcolm Donaldson's[4] proposal that such local efforts should be coördinated by a central body

A DOCTORS ORCHESTRA

IN some countries the music-loving members of the medical profession have formed orchestras and it has been suggested that an orchestra should be set up in London, which might in due course perform at social functions of the profession and at charitable events. Medical and dental students doctors, dentists, and members of their families who are interested in this venture and who play orchestral instruments or who wish to help in other ways are asked to write to Dr H Ucko 14 Upper Wimpole Street London, W 1

University of Sheffield

Prof L J Witts will deliver the address at the opening session of the faculty of medicine in the Firth Hall of the university at 5 P M on Thursday, Oct 8 His subject will be the Opportunities of Medicine

British Association of Physical Medicine

The association is holding a postgraduate course in physical medicine on Saturday mornings from Oct 31 to Jan 23 Further particulars can be obtained from the hon secretary of the association, 45, Lincoln's Inn Fields, London, W C 2

Institute of Child Health, London

Prof E Husfeldt (Copenhagen) will deliver the Alex Simpson Smith lecture at 5 P M on Monday, Oct 26, at The Hospital for Sick Children, Great Ormond Street, W C 1 His subject will be Hiatus Hernia in Adults and Children

Society for Cultural Relations with the U S S R

The meeting of the society announced in these columns last week has been postponed to Thursday, Oct 22, when, at 7 30 P M, at 14, Kensington Square, London, W 8, Dr Brian Kirman will describe his recent visit to the Soviet Union

Empire Rheumatism Council

On Friday, Nov 13, at 2 P M, at 1, Wimpole Street, London, W 1, the council is holding a symposium on phenylbutazone, when the speakers will include Dr Otto Steinbrocker (New York) and Professor Domenjos (Saarbrücken) Tickets may be had on application to the secretary of the council, Tavistock House (N), Tavistock Square, W C 1

Congress of Obstetrics and Gynæcology

The fourteenth British Congress of Obstetrics and Gynæcology will be held at Oxford from July 27 to 30, 1955 The following subjects have been selected for discussion the rôle of the qualified midwife, the family practitioner, and the obstetric specialist in the conduct of normal labour, and the ætiology, prevention, and treatment of pre eclamptic toxæmia of pregnancy Gynæcological subjects will be announced later Further particulars may be had from the secretary of the congress, Maternity Department, Radcliffe Infirmary, Oxford

W.H O Regional Office for Europe

The European regional committee of the World Health Organisation, which is holding its third session in Copenhagen, has recommended that the regional office for Europe should be permanently installed in Geneva, but that the office should be housed outside the Palais des Nations where the world headquarters of W H O are established For the last two years the European Regional Office has been working temporarily in the Palais des Nations This recommendation will be submitted for approval to the W H O executive board at its meeting in January

Ophthalmological Society of the United Kingdom

The annual congress of this society will be held in the department of chemistry, University of Durham, Newcastle upon Tyne, on April 22, 23, and 24 Mr R C Davenport, Dr S P Meadows, and Prof J B Duguid will open a discussion on Inflammatory Vascular Diseases Affecting the Eyes, and there will also be short symposia on Cyclodiathermy, Changes in the Incidence of the Eye Affections of Coal miners in the Past 25 Years, and Gonioscopy Further particulars may be had from the hon secretaries of the society, 45, Lincoln's Inn Fields, London, W C 2

United States (F O.A) Research Fellowships

In response to a request from the Organisation for European Economic Coöperation, the United States government, through its Foreign Operations Administration, has provided over a million dollars to enable 150 young scientists from Europe to study in American research institutions for up to two years

About 25 fellowships will be open for award to candidates from the United Kingdom, and the Royal Society is to advise on their selection No age limits are specified but it is expected that most of the successful candidates will be between 26 and 32 years of age Applications will be considered from candidates who propose to do research in the natural sciences and in the engineering agricultural and medical sciences but excluding clinical medicine They must have a doctorate in science or equivalent experience Applications which may be made at any time will be considered at regular intervals For the first two sets of applications the closing dates are respectively Oct 1 and Nov 30 Forms of application and further information may be had from the assistant secretary of the society Burlington House London W 1

Institute of Dermatology

A series of semi permanent exhibitions will be shown institute during the winter course The first, from Oct. 24, by Miss A Gretener, will be on Medical Ill Dermatology

Foot Health Week

The Foot Health Education Bureau of the Central for Health Education, with the Birmingham health education departments, is to hold a foot health Birmingham from Oct 26 to 30, at the Midland

Abortion Law Reform Association

A meeting of this association will be held on Oct 21, at 7 P M, in the Conway Hall, Red Lion London, W C 1, to discuss the Bill to Amend the Law to Abortion. Mr Douglas Houghton, M P, and Mr Reeves, M P, hope to take part

Yorkshire Association of Graduates of University

The annual dinner of this association will be held on The guest of honour will be Mr W W Galbraith, of the Royal Faculty of Physicians and Surgeons of The hon secretary, Mr James Wishart, may be at 33, Manor Row, Bradford, 1

Princess Tsahai Memorial Fund

Mr Richard St Barbe Baker, leader of the expedition to the Sahara, is to give a lecture, on of the fund, at B M A House, Tavistock Square, W C 1, at 3 P M, on Tuesday Oct 13 Admission free, reserved seats (5*s*) may be had from the hon. of the fund, 3, Charteris Road, Woodford Green, Friends who are unable to attend are asked to send to Lord Horder, the hon. treasurer, c/o Messrs Prideaux, 9, Camomile Street, E C 3

Junior Hospital Posts

In the Sheffield region in May this year there junior hospital posts vacant, of which 31 had been for three or more months, and the regional hospital are submitting a report to the Ministry of Health out that "The present grade of Junior Hospital Officer, £700–£1000 per annum, is not an acceptable ment" The report goes on to suggest that in hospitals, or in those in unattractive areas, these posts be "weighted" by at least an additional £100 a that in hospitals which are regularly understaffed the staff should receive financial recognition of their work

N A P T Hunter Scholarships

The National Association for the Prevention of T offers to doctors and medical students four scholarships possible through the generosity of a private donor, known as the Hunter scholarships

The first is a postgraduate scholarship (£350) to enable a of a British medical school resident in the United King spend some six months abroad studying the control of tu The second is a scholarship (£350) to enable a young any medical school in the British Commonwealth outside the Kingdom to study tuberculosis in Great Britain Two scho (£150) are also offered to medical students who have been capped through tuberculosis to enable them to complete training at any medical school in England or Wales The date for applications is March 31, 1954 and further may be had from the N A P T Tavistock House North, Square, London W C 1

CORRIGENDUM *Placental Blood flow*—In the penu paragraph of Mr John Sophian s letter of Aug 15, the *increased* was omitted The sentence should read

By interpolation we are left to conclude that reduced blood flow due to myometrial tension is linked with renal biochemically detectable, in which diminished glomerular and increased renal blood flow occur

---

Prof C W Asling (University of California), who has Fulbright award is spending a year in the department of of the University of Liverpool to collaborate with Prof. Harrison in research on the endocrinological factors concern arthritis in the rat

The British Epileptic Association has published a giving details of ten colonies for epileptics which will help to choose the institution best suited to their patient's Copies (1*s*) may be had from the association, 136, George London W 1

A new film, produced by the Wellcome Film Unit in collab with the Wellcome Research Laboratories describes the 'Nalorphine' (N allylnormorphine) in antagonising the morphine and other drugs with a similar action The film borrowed on application to the Public Relations Officer Wellcome & Co 183–193 Euston Road, London N W 1

VERNUTRITION AND UNDERNUTRITION

I CAUSES*

R A. McCance

O.B.E., M.A., M.D Ph.D Camb F.R.C.P., F.R.S

ROFESSOR OF EXPERIMENTAL MEDICINE IN THE UNIVERSITY OF CAMBRIDGE

rom the Medical Research Council Department of Experimental Medicine Cambridge

LECTURERS nowadays seem to make themselves famous y confounding their audiences with accounts of their test and most spectacular discoveries in subjects which re themselves only a year or two old The profundity f their investigations is usually enhanced by the nguage in which they describe them, for they never refer o any substance by its proper name if this can be coded nto a string of capital letters, sometimes followed by full tops You will realise at once that I have abandoned ll hope of achieving distinction in this way by having hosen as my title the time worn theme of ' overnutrition nd undernutrition ' and yet I feel justified in having one so for the subject is just as important as nuclear hysics or nucleoproteins The world today is facing roblems in nutrition which will not be solved by food lone (Russell 1949 Boyd Orr 1950 Dodd 1952) and n spite of our clinics for obesity the threat of famine—he greatest famine the world has ever known—hangs ver this country like the sword of Damocles (Fenelon 952 Massingham and Hyams 1953)

Much has been written about undernutrition in the st ten years, and it is quite unnecessary even if it were ssible to try to review the whole subject here Keys, rozek, et al (1950) have produced a monumental work n the subject with nearly 3000 references Lamy et al 946a–f) Hottinger et al (1948) and Helweg Larsen al. (1952) have provided detailed information about mine as it was seen in the concentration camps, and edical Research workers have given an account of ilder undernutrition as it affected the population of a erman industrial town (Medical Research Council 1951)

The unlimited amounts of food which have been ailable *to most of the industrialised and prosperous* mmunities have tempted many people in them to eat o much This, coupled with the increasing importance vascular diseases in their ageing populations, has forced th clinicians and investigators to pay attention to the bject of overnutrition. Work on obesity has been tensive for many years some of it very exact (New rgh and Johnston 1930 Moller 1931 Conn 1944 ewburgh 1944 Rynearson 1951) and new ways of ploring its effects on the composition of the body have en devised (Behnke 1942 Edwards 1950 McCance and iddowson 1951) *The results of these investigations* ve been published and are available

I have, therefore in these lectures tried to concentrate ainly on aspects of the subject which have perhaps t been fully appreciated Clinicians for instance have ways found it very difficult to accept the principles of ermodynamics, and have tried to escape from them ain and again in order to explain the weaknesses of emselves and of their fellow men There has been a dency moreover to think of overnutrition and under trition as two quite separate pathological states and little attention has been directed *towards finding* out w and where they converge into that broad and ill fined fairway of normal nutrition which lies between ry little is known about the importance of keeping strictly in the centre of this fairway and almost nothing about the possibilities of a planned departure from it The burden of my song will be calories—and to some extent proteins They are not so popular as the vitamins today but they are just as important interest in them will return

First Principles

Life as we know it consists in the metabolism and exchanges of protoplasm, and requires for its continuous existence a source of energy and a supply of nitrogenous material in some form or other to replace wastage At some period of their lives all living cells have the capacity of increasing their protoplasmic mass This constitutes growth and demands the supply or synthesis of all the protoplasmic constituents of the cell The bulk of these contain nitrogen If at any time the supply of energy exceeds their immediate requirements organisms have *the capacity of storing it, usually in the form of carbo*hydrate or fat. If the provision of energy is insufficient living creatures draw upon their store and lose weight

These basic principles are beautifully illustrated by unicellular organisms These organisms have great capacity for growth which itself creates enormous demands for energy The best way to observe them storing fat is to study them at a time when growth is for some reason limited while at the same time the provision of energy is not Growth may be restricted for this purpose by reducing the supply of nitrogenous material to the quantities necessary for the replacement of wastage. This can be done very simply in diatoms by placing them in sunlight in distilled water (von Denffer 1948–50) Nitrogenous katabolism can be neglected in such plants *if photosynthesis is allowed to go on Consequently they* lose none of their cell mass and merely deposit storage material in the form of carbohydrate and fat The same sequence of events takes place as a culture of green algæ uses up its growth promoting materials (Spoehr and Milner 1949 Fogg 1953) Some green algæ produce chemicals which accumulate in the culture medium and inhibit cell-division (Pratt and Fong 1940 von Denffer 1948) In the presence of light this leads to the storage of large amounts of fat, and the whole process can be compared with adult life in more complicated organisms. Some *Chlorellas* which were grown for me by Dr G E Fogg had an average cell volume of 80 c μ when the colony was young and 120 c μ after the cells in it had become old and fat The dry matter of an old *Chlorella* culture may contain 70% (Aach 1952) or even 85% of fat (Spoehr and Milner 1949)

If protozoa are removed from their normal environment and placed in a salt solution or distilled water they continue to swim about actively but they cannot grow They lose some of their protoplasmic mass by irreversible degradation and they dissipate much of their stores of fat In consequence they *lose weight and get very thin* Exactly the same process goes on in green algæ if they are kept in the dark. *Tetrahymena pyriformis* can be grown successfully on a synthetic medium containing a mixture of amino-acids (34%) and glucose (66%) Dr L D Hamilton and I have been studying the effect of keeping these organisms in a mixture of glucose and buttermilk which contains 16% protein 81% carbohydrate and 3% fat This diet provides a little fat and more carbohydrate than the other but much less protein Consequently it has the effect of limiting the growth rate of the organisms relative to their capacity to synthesise fat, and the result is that they get very obese (fig 1)

Adjustment of Intake and Expenditure

The drive to eat and the desire to drink are essential instincts for survival. But how are the impulses controlled ? Many writers on this subject have words hunger thirst appetite and satiety

---

The first Humphry Davy Rolleston lecture for 1953 delivered before the Royal College of Physicians on May 5 The second lecture will be published in a forthcoming issue.

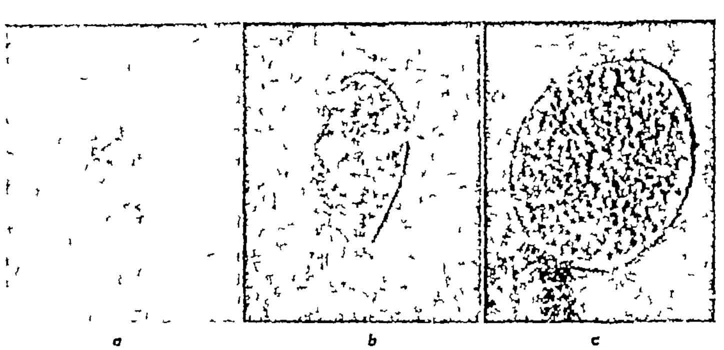

Fig 1—Effect of overnutrition and undernutrition on the protozoon *Tetrahymena pyriformis* a, after being grown on a good medium (see text) and then starved, b a normal individual grown on a good diet, c, an obese individual grown on a buttermilk glucose medium (× 1200)

closely defined (Bruch 1940), these words have such strong and such different subjective meanings that it is impossible to use them objectively A rat knows nothing about the differences between hunger and appetite, and all the work on this animal (Adolph 1947) shows that the word satiety, as we interpret it, has no place in its *modus vivendi*—yet something keeps the normal rat in water balance and calorie equilibrium People usually drink more water than they need, but there is little if any possibility of drinking too much, because all animals are provided with a mechanism for correcting this, and, no matter how great the indiscretion, the kidney can be relied upon to restore and maintain within narrow limits the volume and composition of the fluids in the fat free parts of the body The amount of water in the body, therefore, is regulated as a rule by the control of output The desire to drink, however, may not be strong enough in hot climates to keep people fully hydrated (McCance and Young 1944, Adolph et al 1947) and its complete suppression is much more rapidly fatal than a total abstinence from food No one appreciated until too late that the famous Welsh Fasting Girl would die of dehydration, but she did so long before anyone was expecting to see her succumb to a lack of food (Fowler 1871) Dehydration has been the cause of far more deaths than starvation among shipwrecked personnel and may have been responsible for some of the failures to reach the top of Mount Everest

Before discussing how the calorie balance is adjusted, it is well to say a word or two about how accurately this is usually done The food of the "average" man has often been found to provide about 3000 calories a day, but the figure varies very much from one individual to another, and in any group of 20 or more men or women, or boys or girls of the same age, there is likely to be one who appears to be eating a diet which provides him or her with twice as many calories as another (Widdowson 1947) Since both may well be maintaining their body-weights at a steady level, and since variations in digestibility and absorption may for practical purposes be neglected, it follows that the energy expenditure of different individuals must also vary How does a person know just how much food to eat to meet his own personal calorie requirements? If the "average" man takes 9 calories per day more than he requires he will only be 0 3% "out" in his adjustments Few chemical assays in the biological field have an accuracy approaching this (Wootton and King 1953), and this error would mean a gain in weight of only 1 gramme of fat a day—about 0 000014% of the weight of the body This does not sound very important, but in matters of this kind "the little more and how much it is," or (in language less poetic than that of Robert Browning) this error, if cumulative, would amount to 15 lb in twenty years This gain in body fat is possible only because the surplus fat is continually being removed from active participation in processes of the body and stored in a rel unreactive state Such an accumulation not be tolerated with an active electrolyte sodium As a matter of fact this is the sort error that most people make as they appr middle age, for the "normal" or "averag weight for a given height is about 15 lb m in the forties than it is in the twenties (Me politan Life Insurance Tables, Stern 1949) this added weight is largely due to fat (Br 1952)

Expenditure of Energy

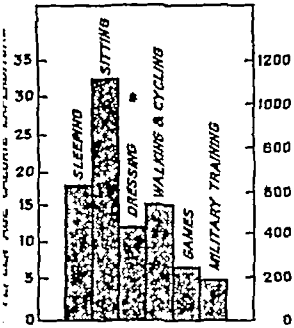
In collaboration with Dr O G Edholm, I E M Widdowson and I have recently studying the food intakes and energy exper tures of a group of active young men in train for the Armed Forces Methods have be developed recently by which the energy expenditure tasks involving *considerable muscular movement* exertion can be obtained relatively easily, and we expect more information on this aspect of prac physiology before long We were not able to apply the newer methods, but Dr Edholm pursued the and cooperative young men with pencils and paper, even from time to time with Douglas bags He could of course, keep them all under his eye for the whole the week, but he made them write down everything did during each half-hour of it Two brains may better than one for some purposes We cannot pre however, that the Edholm-Widdowson combin balanced out these peoples' calories as well as each was capable of doing it for himself, for Dr Widdow found that the young men's food provided each of with an average of 3705 calories a day, while Dr Ed working quite independently, calculated that energy expenditure amounted to 3427 calories two investigators were, therefore, nearly 300 calories on their "balance" Dr Edholm's results do, howe give us a very good idea how the calories were used The table shows the figures he adopted for som the tasks these men carried out, and the times spent on them, and fig 2 shows how the 3427 were distributed among the different occupations comparison of the two is very instructive Sleeping sitting down at lectures and similar jobs, did not re many calories per hour, but even these hours spent of time over them and they accounted for 1715 cal per day—nearly half of the total Walking and cyc about between the lectures and in pursuit of their tasks used up more of their energy than anything they did except sleeping and sitting These are rhythmical activities which can be sustained for hours end and if indulged in to any extent soon use up a number of calories Squash is a very energetic but the time spent upon it is necessarily limited,

ENERGY DEMANDS OF CERTAIN OCCUPATIONS AND AVERAGE TIME SPENT UPON SOME OF THEM

Occupation	Cal /70 kg /hr	Hr /day	Occupation	Cal /70 kg
Sleeping	60	8½	Standing	139
Sitting	112	9¼	Darts	146
Dressing changing, cleaning personal equipment &c	200	2	Snooker	156
			Cricket	154
			Running	522
			Squash	543
Walking	418	1		
Cycling	500			
Sports (as a whole)		¾		

ames as a whole only accounted for 256 out of the 3427 alories. Notice, furthermore, that more of their energy ent on dressing, changing and cleaning their personal quipment than on their practical training

The expenditure of energy is largely dictated by cir umstances and opportunity Some men have to run for twenty minutes every morning to catch their train others get to work in three quarters of an hour on a cycle while others again move mostly by car and elevator The energy men and women are called upon to expend, more over may vary widely and without warn ing from day to day Edholm found that the adets varied their *caloric expenditure during the week of* bservation over a range which averaged 775 calories per ay Stability of weight is often maintained over periods f years by an adjustment which is very exact but it is erfectly certain that the adjustment may be widely ut over short periods of time. Most people overeat, for xample on Christmas day and some of them upset eir calorie equilibrium still further on that day by aking less exercise than usual Many take violent or rolonged exercise over the weekend and few know nough about food values even to attempt to equate their eekend calories to it Animals never could. Yet a child 8 months instinctively and without direction will ake just the right amount of food for its maintenance nd growth (Davis 1928 1939) and a mouse or a rat will crease its *food* intake *to* many times its usual level uring a full lactation and drop it again immediately terwards to maintain an almost constant body weight Kennedy 1952) Observation particularly of animals hich cannot be expected to exercise any conscious ontrol of their intakes indicates that the expenditure energy is directed by opportunity external compulsion d physiological requirements The intake of energy adjusted to meet these demands. Calories are the only quirements to be met constantly like this, although at of water may be at times and if the contents of the t be regarded as lying outside the substance of the dy proper then the requirements of iron can be nsidered as being met in a similar way (McCance and iddowson 1937 1943 Hahn et al 1943) The mecha-sms by which the intake of calories is controlled must w be considered.



ig 2—Actual and percentage of total calories expended on various activities.

The Drive to Eat

In a really primitive state it was probably impossible eat too much, certainly to do so for months on end ood was too hard to come by and the time and oppor unity to eat it were lacking Enormous meals must have en taken from time to time but the fat man would on have lost the race *when survival went to the swift* Voracious desire to eat however was probably an set in the struggle Cooking must have been primitive hen there was any cooking, and food even if plentiful as probably not very easy to eat One can only eat too uch if one can get too much Obesity in other words sults from leisure and plenty It is one of the troubles of civilisation, but all civilised people are not troubled by it. A man gets too fat only when the natural control of his food intake has failed.

A desire to eat is often associated with contractions of the stomach and at one time these were thought to be the cause (Cannon and Washburn 1912 Carlson 1913 Hollander 1940) These contractions can be felt by a man and make him want to eat but dogs with their vagi cut still attack their food (Grossman and Stein 1948) and there are certainly other incentives. The nose, the eyes, the ears, and memory with everything it represents in cortical integration are all involved

When insulin had been discovered and its effects began to be explored it was soon found that one of the results of a low blood sugar was a desire *for food* Insulin has in fact been used extensively as a drug to stimulate this but its clinical effects have been attributed by some people merely to suggestion (Freyburg 1935) Mayer and his associates (Mayer 1952 Mayer and Bates 1951 1952 Mayer et al. 1952) have taken up the subject again and carried out more experimental work They believe that there is a glucostatic mechanism for regulating the intake of food Their idea is that the drive to eat, in all its manifestations, is caused by a fall in the level of circu lating blood-sugar or more precisely by a change in some high-energy bond equilibrium within some sensitive cells which depends upon this level They have shown experimentally that injecting glucose or adrenaline decreases an animal s food intake whereas insulin puts it *up and sucrose and fat emulsions are without effect* Similar experiments have been carried out by others (Hanson and Grossman 1948 Janowitz et al 1949 Janowitz and Grossman 1949), not always with the same results Mayer has also used hypophysectomised alloxan treated animals as test objects and studied the relation ship in man between arteriovenous glucose differences and the sensation of hunger which is felt only if the difference is small The ravenous urge to eat in a simple untreated diabetic he attributes to the failure of the sensitive cells to metabolise the glucose circulating in the plasma It may be added that low blood-sugars have been found in human undernutrition, and death has even been attributed to the fall (McCance 1951)

Most will agree that a case has been made out for *regarding a fall* in blood-sugar as *one* of the things that make people want to eat but there must be more Absence from food makes for generalised nervous activity of which contractions of the stomach may be one mani festation a keener sense of smell (Goetzl et al 1951–52) and irritability others. It is possible that a fall in some essential material within the nerve-cells or their end organs, rather than in the medium outside them may be the cause of the nervous activity restlessness, and reflexes which initiate the desire for food.

The Stop " Mechanism

Protozoa may be prepared to eat for twenty four hours a day and it may be impossible to satisfy their appetites if the food supplies everything that they require for growth Not so the simple hydra however which ceases to feed or to make any response to food when it has been very well filled (Buchsbaum 1953) Most animals and certainly man do not eat continuously even if they get the chance They stop I suggest, because food is one of the oldest and greatest sedatives It acts thus even in animals like hydra which possess only the most primitive nervous systems, and it does so by abolishing that activity *and restlessness which had initiated the drive to eat* There is a little experimental evidence that this is true at any rate in man; for Goetzl et al (1951–52) have found that the sense of smell becomes less keen after a meal even after one with no smell like sucrose If the effect of food is to replenish nerve-cells with oxidisable osmotic, or structural materials it is possible to explain not only the effects of a single meal but also the sustained voracity of the really undernourished (Widdowson 1951), for it may take a long time to rebuild the essential structures within the nerve cells One may recall for something comparable the length of time it takes to restore the serum cholinesterase to normal levels in people who have been undernourished (Hutchinson et al 1951) At present these ideas are but idle thoughts, for they have yet to be explored by experiment, but they may turn out to have been of some scientific value when these very fundamental problems have been solved

Little as we know about the mechanisms which restrain the primitive urge to eat, we do know a number of times and ways in which the adjustment between calorie intake and expenditure may break down A study of them tells us something about the controlling mechanisms in the higher animals and also shows us where more knowledge would be very helpful

Breakdowns in Mechanisms Normally Adjusting Intake to Expenditure of Calories

SCARCITY

Under the heading of scarcity must be classed all the degrees of undernutrition which result from economic stress, war famine, and the like These are purely physical causes, and so obvious that they need only be mentioned for the sake of completeness The same applies to the undernutrition which follows in the wake of physical diseases like cancer, particularly of the œsophagus or stomach, and other gastro intestinal abnormalities In all of these, intake fails to keep pace with requirements

PHYSIOLOGICAL REASONS

Periods of physiological overnutrition and undernutrition are part of the life cycle of some animals The young Atlantic seal, for instance, becomes extremely fat during the first few weeks of its life when it is being suckled by its mother The parent thereupon leaves her offspring to its fate on the beach and takes to the sea again, and the young seal lives on its own fat for the next few weeks before it attempts to follow its mother to the open sea and to hunt for its own food Some sea birds go through similar stages in their development, and a marmot (Morgulis 1923) may get fat enough during the summer to lose up to 40% of its weight during hibernation There seems to be a tendency for most animals to eat more than their immediate requirements if the food supply gives them the chance Perhaps the most dramatic example of physiological undernutrition is provided by the migrations of the spawning salmon, but these must be considered as bordering on the pathological, for the Pacific salmon all die after spawning Guineapigs, unlike most other animals except man, are quite fat at birth, and weaning begins at once It would perhaps be better for the young guineapigs if they were not so precocious, for most of them, in consequence, go through a fortnight or more of physiological under nutrition Most of these physiological departures from normal nutrition are entirely instinctive The higher centres are not involved Given the right conditions the results are as inevitable as they are in the protozoa

PSYCHOLOGICAL REASONS

Many people who are worried by the cares and troubles of this life find relief in eating and in the mental rest which follows it (Babcock 1948) "Fate cannot touch me, I have dined today" is the basis of a great deal of obesity Food must be compared to alcohol in this respect, and the victim may be anyone from a harassed and successful company director to a miserable and flagrantly psychopathic woman We have recently had the opportunity of studying a boy of 14 who now weighs 16½ stone (104 kg) mainly because of the psychological support he derives from overeating While he was in hospital he was given a free run of the kitchen services for a and his food was found to be providing him with calories per day Up till now all attempts to do an for him have been frustrated by his own mentality by his foolish and indulgent mother

A woman may lose all control of her food intake d pregnancy, immediately after delivery, or during tion She may eat ravenously and become immen fat in a very short time These interesting cases h been investigated by Sheldon (1949) under the gen title of maternal obesity

The very things which drive some people to prevent others from taking enough of it Worries troubles are such a common cause of a loss of wei that there is no need to elaborate on them During a continuous fast which has been undertaken f bravado, religion, or gold, the desire for food is said t pass off after a few days, but the men and women wh do this kind of thing are not psychologically normal, a this is only one example of hunger being abolished b emotion (Morgulis 1923) Sexual activity provides striking inhibitions in the animal world and may quite forcibly in man Except in psychotics and in you women with anorexia nervosa, hunger generally beg to assert itself before the undernutrition has serious It is easier to get too fat than too thin

Psychological breakdown of control clearly invol the highest nervous centres, and in man it is obvious t the cortex is an important link in the chain of contr Some patients who have had one of their frontal lo removed on account of a new growth get very f (Rylander 1939) and so also do some who have b leucotomies (Partridge 1950)

It is difficult to classify all the causes of psycho breakdown A man often puts on weight for a time af getting married, or after giving up smoking A sud change of diet from one which is bulky and of low ca value to one which is just the reverse may so dec the body and the psyche that a gain in weight is immediate result This was well illustrated by behaviour of the subjects in our Experimental Stud Rationing (McCance and Widdowson 1946) The mental diet on which the party had been living for previous three months had been a bulky one and contained very little fat At the close of the experi four persons who had become accustomed to this found themselves free to eat what they chose Th continued to eat up to the anatomical capacity of stomachs, but they replaced some of their cereals vegetables with foods like fat and sugar, of high calo value but of negligible bulk The result was that, the end of the first week of freedom came, two of subjects were found to have been eating food provid them with about 1500 calories a day more than accustomed amount—and the result was an inevit gain in weight People who have lost control for reasons usually regain it again, sometimes quite su They may merely cease to gain weight, and stabilise at a new level, or they may revert to their original we over the next year or so

A CHANGE IN REQUIREMENTS

If adult rats are confined in very narrow cages (I 1949) they become obese This has its counterpart human experience, for a person often gains weight if buys a car and ceases to take his usual exercise, or if is confined to bed with some trouble which does interfere with his appetite or metabolism The co is less common, but I know a man who regularly l many pounds of fat on his annual mountaineering hol and relied upon it to keep his corporation wit reasonable limits

In these instances one must suppose that the c in requirements failed to register on the control me n, probably because within the time of observation the ıulus was not strong enough to break through a tern of behaviour previously acquired We may ıpare the way in which quite severe dehydration may ımes be tolerated by the centres controlling the intake vater, even though it leads to a loss of bodily efficiency

AGE

ıdvancing age is probably the commonest cause of intake failing to conform to requirements Its effects obvious in both man and animals and numerous sons probably contribute to them a reduction of ivity being one The balance nearly always swings rards obesity at first and a pleasure in food may be ained until very old age but old age and all that it olves sometimes makes a man apathetic and inclined give up the struggle to provide himself with all the d he needs, but for which the zest has gone (Hobson l Blackburn 1953)

EXPERIMENTAL BREAKDOWN

d Salts

ıpart from immobilising an animal and overfeeding it removing its testes or ovaries which may produce its ects by reducing activity obesity has now been duced experimentally in a number of ways which all er scope for further study and development Brecher l Waxler (1949), for instance found that if mice were en a single large dose of aurothioglucose, about half animals lost control of their calorie intake, doubled ir weight or more, and became very fat. No lesions re found in the brain, hypophysis or thyroid, or leed in any of the other organs likely to have been ponsible. Further work will no doubt discover the nection

redity

Danforth (1927) produced a strain of mice with a nounced tendency to develop obesity The trait is ociated with a yellow colour

Danforth showed that these mice were usually rather aller than their littermates at birth and were two or ee times as heavy eighteen months later They ate more food Mayer et al. (1951) found that the obese ce tended to select a diet which contained much fat ereas their littermates chose one which was mainly rbohydrate. Guggenheim and Mayer (1952) believe at these animals have an abnormally low capacity for oxidation of acetate. This leads to an increased ilisation of acetate for the synthesis of fat. Their idence, which is based upon the use of radioactive rbon compounds is not altogether convincing Whether not there is a perversion of acetate metabolism wards the synthesis of fat Danforth (1927) showed that fat in these animals could be mobilised and oxidised ite normally if the animals were not given enough food

ırther work on this syndrome may help us to under ınd some of the cases with which we are all too familiar the outpatient departments

ypothalmic Lesions

A third way of disorganising the control of food intake s been by the puncture and destruction of two small l on each side of the hypothalamus. As with some her great advances in physiology the lead came from e clinicians (Mohr 1840 Paget 1891 1897 Fröhlich 01 Duncan 1924 Evans 1937) who described the sociation of obesity with lesions of this part of the ain Destruction of the two lateral nuclei has been found give rise to complete anorexia, and obesity has been oduced successfully in dogs cats, monkeys (Ranson al. 1938) and rats (Brobeck 1946 Brobeck et al 42–43a) by puncture of the two medial nuclei.

Immediately after the latter operation the animals hibit the most voracious impulse to eat. They gain ight with great rapidity for a time and the increase er the control animals is due almost entirely to fat. this stage they continue to provide themselves with far more calories than they require even if the food is made unpalatable by mixing it with kaolin or by giving the animals a limited amount of water Mayer (1952) has found them to have very low blood-sugars.

After a time they gradually re-establish control of their caloric equilibrium and cease to gain weight At this stage they are found to be eating no more or very little more than the controls. When they have regained caloric equilibrium after getting very fat they become distinctly 'choosey' about their food Making it more palatable leads to a further gain in weight and making it very unpalatable may cause an extensive loss of weight. At any time after operation a reduction of weight brought about by compulsory starvation or an unpalatable diet is rapidly made good as soon as the original food is restored

If normal rats are starved or undernourished for a time, they rapidly make good any weight they may have lost when they get the chance but they react quite differently to alterations in the palatability of their food for they tend to maintain a constant weight by linking their caloric intake very closely to their caloric expenditure When normal rats however, get very old and fat they tend to behave rather like the operated animals that have got fat (Brobeck et al 1942–43a, Bruce and Kennedy 1951, Kennedy 1950 1951, 1952)

The enormous intake of food of these animals after operation puts a severe strain upon their carbohydrate metabolism but they do not usually excrete glucose (Brobeck et al 1942–43b) The stored fat can be mobilised freely if the caloric intake is reduced and there is nothing to indicate that there is anything abnormal about their fat metabolism. The gain in weight and its consequences are wholly the result of eating too much food. The lesions may also lead sometimes to side-effects particularly in water metabolism (Stevenson 1940 Bruce and Kennedy 1951)

Clinicians will recognise many points of resemblance between the behaviour and pathology of these animals and of the patients who attend their obesity clinics The ravenous food consumption for a time after pregnancy; the re-establishment of control on quite a moderate intake of food but at a much greater weight, the tendency to return to this weight after it has been reduced and the fat old gourmet always looking for more palatable food and gaining weight on it may all be recognised

Cortisone

Many people treated with cortisone lose control of the balance between calorie intake and requirement (Sprague et al 1950) Hench et al (1950) reported that 11 out of 21 of their patients developed tremendous or insatiable appetites and one of them was found to be taking in 6000 calories per day Hench et al (1950) pointed out that no prediction could be made as to which patients would react in this way and that the magnitude of their response bore no relation to the benefits of the treatment on their joints. The patients all gained weight, sometimes a great deal of weight and this was in the main due to a gain in fat and muscle The retention of water and salt which might also be brought about by cortisone was a complication but only a minor one

No-one at present can say how cortisone makes people react in this way but there are two possibilities Firstly cortisone produces in some people a sense of well being and euphoria which might break down the usual critical control exercised by the cortex and make these people overeat like those who have had a leucotomy Secondly cortisone decreases carbohydrate tolerance increases the resistance to insulin and may lead to frank diabetes With the doses used by Hench et al. (1950) these effects were small and were considered to be functionally unimportant but if Mayer (1952) and his co workers are right in suggesting that the control of food intake normally depends upon the level of circulating glucose available—i e utilisable in some sensitive cells in the body—then this may be the explanation Only further work preferably quantitative work will decide

Natural Experiments

Tumours and other abnormalities of the ductless glands may break down the normal adjustment of food intake to food requirement Thyrotoxicosis always increases the demand for calories This is usually not met by an equivalent rise in intake, why not, we do not know, and a loss of weight is the result Some patients with thyrotoxicosis, however, do not lose weight and may even get fat In them, presumably, the mechanism of control remains intact and the drive to eat may even be so highly stimulated by the demand for calories that it makes the patients over react Simpson (1952) has put forward the case for the adrenals and islet tissue Ductless glands must act through their hormones—thyroxine, insulin, cortisone and so on—and the way in which these hormones act has been discussed Hormones may modify the proportions of protein, fat, and carbohydrate normally broken down, and the adrenal hormones may alter the sites in the body upon which fat is deposited, but these hormones can only induce generalised overnutrition or undernutrition by upsetting the mechanisms which normally adjust intakes to requirements They might be used more extensively to further our knowledge of these mechanisms

The Network of Control

From this jumble of observations and experimental facts it would appear that many things must be involved in the control of calorie equilibrium A few of the known ones may be

(1) A humoral mechanism depending upon the level of glucose and other metabolites in the plasma These may supply the nerve-cells with materials which produce widespread changes in activity and behaviour

(2) Fully coördinated nervous "centres" at some level in or below the hypothalamus These are normally "set" by humoral or nervous influences to produce uncontrollable hyperphagia They may conceivably be the two lateral nuclei in the hypothalamus.

(3) Two medial foci *in the hypothalamus which restrain* the activity of the centres lateral to them or below them These foci are presumably integrated with the cortex, the sense-organs, and other centres, and may also be actuated by a humoral mechanism They are essential for the physiological control of calorie equilibrium, but, judging by the behaviour of animals after their destruction, control can be re-established in their absence, admittedly only at a level of nutrition which must be regarded as pathological

(4) The cortex In man this is involved at both conscious and unconscious levels Both are extremely important, and the organs of taste, smell, sight, and hearing are naturally implicated as well—as are all the impulses arising from contractions or distention of the stomach

From the practical point of view control is ultimately conscious in most healthy people, and, if they have the knowledge and the strength of mind—and of course the means to obtain all the food they require—their weight is a matter for themselves to decide

RUCHILL HOSPITAL, GLASGOW

THE treatment of tuberculous meningitis with strepto rcin has two main disadvantages: the need for ıtinued intrathecal injections and the occasional ıcity of the antibiotic So far as the injections are ıcerned one must consider not only the long period of ess to the patient but also the possible effect of con ued interference with the cerebrospinal fluid (C.S.F.) repeated lumbar puncture introducing a foreign substance Although it is dangerous to compare an acute disease with a chronic one it is perhaps worth recalling that in meningococcal meningitis intrathecal medication—e.g a combination of serum and sulphonamide—seemed to produce less satisfactory results than did oral sulphonamide alone (Department of Health for Scotland 1944) Some workers have indeed argued that the avoidance of lumbar puncture and the use of massive doses of parenteral penicillin are of benefit despite the poor passage of penicillin into the C.S.F. (Dowling et al 1949) The discovery of the activity of isoniazid against *Mycobacterium tuberculosis* and the finding that it passed into the C.S.F. in effective amount suggested its therapeutic use in tuberculous meningitis We describe here its effects as the main method of treatment in seven cases

Material and Methods

The seven patients were unselected consecutive admissions to one unit which can exercise no control over its admissions but must accept all notified cases

TABLE I—CLINICAL DETAILS OF THE TREATED CASES

Case no	Sex	Age (yr)	Clinical assessment on admission	Isolation of *M tuberculosis*	Mantoux	Family history	Other evidence of tuberculosis
1	M	1½	Intermediate	C.S.F +	+	Mother sputum +	Snowstorm radiograph
2	F	3	Advanced	C.S.F +	+	Mother sputum +	Nil
3	F	16	Advanced	C.S.F +	+	None known	Nil
4	F	20	Intermediate	C.S.F +	+	None known	Pleural effusion
5	F	20	Advanced	C.S.F +	+	None known	Nil
6	M	3	Intermediate	Organism not isolated	+	None known	Nil
7	M	3	Intermediate	Organism not isolated	+	None	Nil

*Classified according to Medical Research Council (1948).

The first patient was admitted in July 1952 and the last in February, 1953 Every endeavour was made to confirm the existence of a tuberculous meningitis immediately after admission

The first four patients received a similar schedule of treatment During the first week in hospital streptomycin and isoniazid were both given Streptomycin was given intramuscularly and intrathecally in a dose suitable to the patient's age and weight After the first week treatment with streptomycin was stopped and thereafter the sole chemotherapeutic used was oral isoniazid 10 mg per kg of body weight daily for sixteen weeks

The fifth patient *had been treated for tuberculous* meningitis with streptomycin in the unit previously and

TABLE II—DURATION OF ABNORMALITY OF CERTAIN CRITERIA

was readmitted in relapse She was now given isoniazid alone 10 mg per kg of body-weight by mouth daily

The last two patients received a course of treatment similar to that of the first four, except that the duration of streptomycin therapy was increased to four weeks

In all the cases a weekly lumbar puncture was done, even after streptomycin therapy had ceased. It should be emphasised that the schedule of chemotherapy was decided at the onset of treatment and was not affected by the condition of the patient

To provide controls treated with routine streptomycin therapy, patients were selected from those treated in the unit during the immediately preceding period An attempt was made to "match" the isoniazid-treated patient with a control of similar age and severity of illness on admission Since all the treated patients have so far survived, the controls were selected from surviving streptomycin treated patients The fifth patient served as her own control

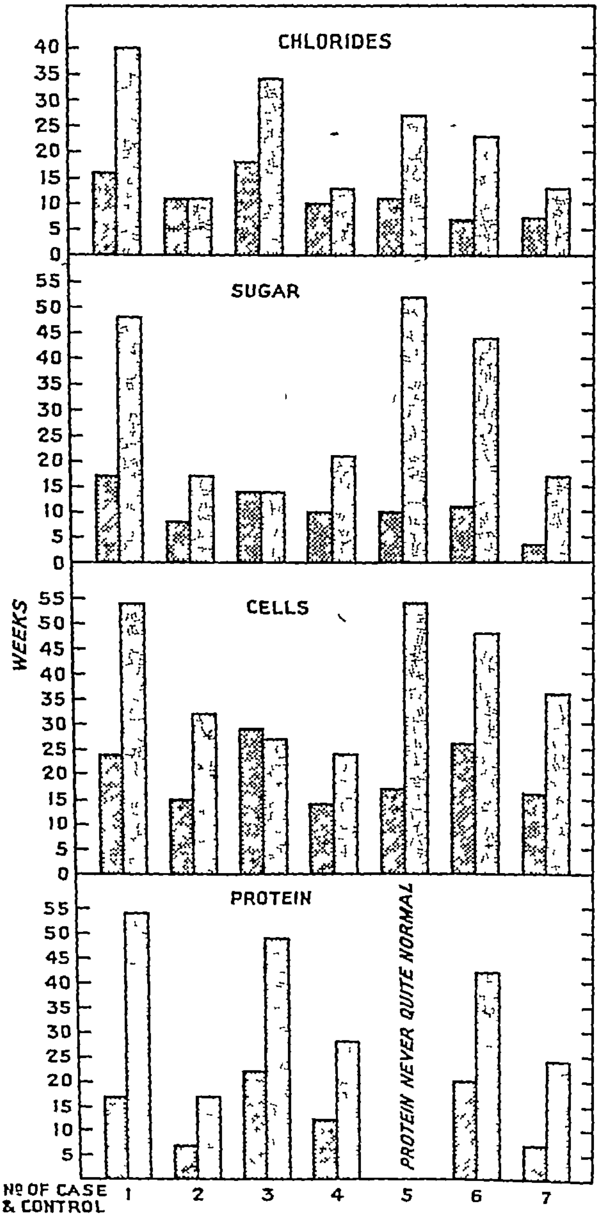

Fig 1—Alterations in amounts of certain constituents of C.S F during treatment hatched isoniazid-treated patients ; stippled, strepto- treated controls.

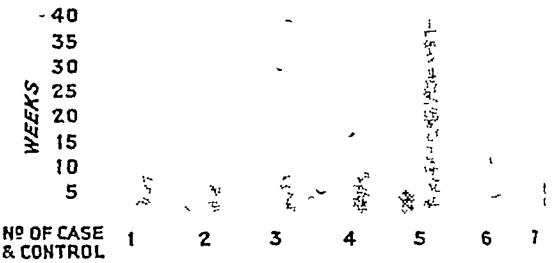

Fig 2—Time taken for temperature to settle : hatched, isoi treated patients , stippled; streptomycin treated contro

Results

Table I gives brief clinical details of the seven pati

As already stated, all the patients have surviv but the longest period of survival is only twelve mon At the present stage we have decided to use as fac of assessment the results of the serial examination of t C S F and the duration of the initial fever The follow were adopted as "normal" findings for the C (1) cells <10 per c mm , (2) protein <40 mg p 100 ml , (3) sugar >45 mg per 100 ml , and (4) chlori >729 mg per 100 ml For each patient in the series for each "matched" control the time which elap until these normal findings were reached was calcul These data are shown in figs 1 and 2, the mean fig are given in table II

Fever

The difference is greatest in the group of patients received a minimal course of streptomycin In t patients who were given streptomycin for four w the initial fever lasted much longer Although t point requires further study, it seems possible that e the intrathecal irritation produced by the strepto or the stress of repeated lumbar puncture may responsible for prolonging the fever

Constituents of C S.F

As regards all the factors chosen for comparison, isoniazid-treated patients returned more rapidly normal So far as the cells and the protein are concern such an effect may not be surprising, since any irri effect of streptomycin, with the production of an "as meningitis," was reduced to a minimum, especially cases 1–4 The more rapid return to normal of the s and chloride content is perhaps more interesting In v of the modern opinion that the chloride content is ma a reflection of the serum chloride level, the questi whether the streptomycin treated patients had persistent vomiting was considered The records did suggest that this had been a major manifestation

Although what might be termed the general pro of the patients cannot be defined in figures, all those observed the patients said that the appearance of cli recovery in those given isoniazid was very rapid appetite improved, there was obvious gain in we and even the young patients were happy and conte at a stage in the treatment much earlier than was previous experience with orthodox streptomycin ther

Discussion

We are aware that the follow-up should be lo and that our method of control is not above repr It seems, however, that isoniazid alone has pr effective in some cases of tuberculous meningitis Fur it seems that the lessened interference with the men and C S F which is possible with oral therapy may advantages in securing a more rapid return to no of the C S F chemistry There is no doubt that the arduous treatment has been advantageous in se a much happier patient and a ward whose morale turbed by the constant repetition of intramuscular and rathecal injections

We do not suggest that isoniazid alone should be garded as adequate therapy for patients with tuberous meningitis. The rapidity with which *M tuberosis* may develop resistance to isoniazid administered ne (Medical Research Council 1953) indicates a need caution, and was our reason for prolonging the course streptomycin in cases 6 and 7 Our series was so all that it does not permit any comment on this point. vertheless these encouraging results support the view at both the total amount of streptomycin and the ration of its administration might be reduced with nefit to the patient's comfort and an increase in rapidity of his recovery

Summary

Seven patients with tuberculous meningitis were given niazid by mouth as the main method of treatment l are alive after a follow up period ranging from six to elve months

The return to normal of the C.S.F constituents was ore rapid than in cases treated in the conventional y with streptomycin

There is a need to examine the best method of utilising ese chemotherapeutic agents in tuberculous meninis with the aim of reducing the amount of intrathecal terference

TREATMENT OF TUBERCULOUS MENINGITIS

WITH STREPTOMYCIN AND ISONIAZID

JUAN TORRES-GOST

AD OF THE CLINICAL DEPARTMENT HOSPITAL DEL REY
RA ENFERMADADES INFECCIOSAS MADRID PROFESSOR OF
FECTIOUS DISEASES IN THE ESCUELA NACIONAL DE SANIDAD

SINCE the introduction a year ago of a new treatment r tuberculous meningitis in this hospital, a considerable ange has taken place in the clinical evolution of the sease and in its prognosis with a striking reduction in e tragic sequelæ that had so often followed in the st.

The arrival of streptomycin had already done much control this disease but treatment with streptomycin one was long tedious, uncertain and difficult, and ere could be no hope that this drug alone would solve e problem In our experience the combination of reptomycin and *p* aminosalicylic acid (P.A.S) may lead permanent cures but the prospects become much tter with the introduction of isoniazid

A Combined Treatment

In May 1952 we began to use a combination of intrauscular streptomycin oral isoniazid and intrathecal oniazid (this isoniazid was specially prepared by the stituto Ibys Madrid) We have adopted the following an to cover three months treatment

tramuscular Streptomycin

Children under 2 years of age : 0·2–0 3 g daily in one dose severe cases, up to 0·5 g

From 2 to 10 years : 0·5 g daily in one or two doses

From 10 to 15 years : 1 g daily in two doses for ten days en 0 5 g daily in one or two doses until the pyrexia subsides.

Adults 1 g. daily in two doses until the pyrexia subsides

Oral Isoniazid

Children under 2 years of age : 150 mg daily

From 2 to 10 years : 200 mg daily

From 10 to 15 years : 300 mg daily

Adults : 400 mg daily

Intrathecal Isoniazid

Children under 2 years of age : 10 mg daily in a single dose

From 2 to 10 years : 20–30 mg according to the severity of the illness.

From 10 to 15 years and in adults 30–50 mg daily, beginning with 30 mg and increasing the dose in 5 mg steps.

This scheme is only a general guide and the doses may of course be changed according to the progress of the illness and the severity of any extrameningeal lesions After more than 12 000 intrathecal injections we have observed no intolerance to this treatment or difficulty in carrying it out In all the patients generally receive in the initial treatment 30–45 g of streptomycin, 25–30 g of isoniazid by mouth and about 55 intrathecal injections—30 in the first month 15 in the second and 10 in the third

Results

The results in the first 100 cases treated with this combination have been very encouraging and there have been only 6 deaths.

Hitherto the disease had been almost invariably fatal, but we were now able to classify the cases into mild, moderate and severe forms The severity it seemed depended less on the meningeal lesion than upon any existing extrameningeal lesions and upon the constitutional resistance of the patient

Mild cases responded rapidly : in a week patients would be free from meningeal and other signs, and though the cerebrospinal fluid (C S F) was slower to respond this did not seem to affect the excellent improvement in their general condition In spite of this rapid response we continued treatment for the full three months These mild forms accounted for about 20% of cases

In the *moderate* cases progress was much slower but none the less satisfactory During the initial acute stage many patients were in deep stupor and the first sign of improvement was usually the return, at times almost imperceptible of contact with the outside world This gradual awakening was usually complete after two or three weeks but in some cases only after two months or longer The acute phase was then followed by a period of one or two months during which the patients had no symptoms of any kind, though abnormalities of the C.S.F persisted. In most patients with this moderate form the body temperature curve is typical. A febrile phase lasting over three weeks, with daily variations of about one or two degrees is followed by a second febrile phase lasting over four weeks and thereafter the patient is afebrile At the end of the second febrile phase the C.S.F is noticeably improved but it does not become normal for a further three months, during which time the patient has received no treatment whatever About 65% of cases were in this ' moderate ' group

The *severe* cases evolved more slowly and responded less satisfactorily to treatment Successive febrile phases followed each other and the general condition did not improve so rapidly as in the mild or moderate cases The persistence of symptoms and signs was often due to extrameningeal lesions especially abdominal tuberculosis The period of convalescence was much longer About 10% of cases were in this group and it is among these that deaths are to be expected

Sequelæ

The sequelæ have been mild A child with hemiplegia of the right side recovered sufficiently to move the leg muscles normally during convalescence, and though weakness of the hand muscles persisted, he could use his hand perfectly well 6 patients had paresis of the tibialis anterior, giving rise to difficulties in walking Another 3 patients dragged one foot on walking, but this improved and was not a serious disability No sensory sequelæ were noted

Follow-up

The suppression of the acute phase does not necessarily mean a permanent cure Only time will tell how efficient this treatment really is and whether the present routine will have to be modified

We have under observation 61 patients who have had no treatment for from three to seven months after the acute phase had been overcome by three months' combined therapy, 34 of them are at home and 27 are still in hospital Those at home were allowed to leave hospital because the improvement in the C S F gave grounds for confidence, and because home conditions were *satisfactory* The 27 cases *still in hospital* consist of two groups a smaller group of 6 patients who, though showing improvement in the C S F, were kept in hospital because they could not afford the journeys from their homes for monthly examination at the hospital, and a larger group of 21 in whom the C S F did not improve as rapidly as in the other cases The outlook for this second group does not seem good, and it is here that relapses have occurred The 61 cases under review are summarised in the accompanying table

RESULTS IN THE 61 PATIENTS WHO HAVE HAD THREE MONTHS OR MORE WITHOUT TREATMENT

PATIENTS DISCHARGED

Months without treatment	No of cases	Cerebrospinal fluid			Relapses
		Normal	1–15 cells per c mm	15–30 cells per c mm	
7	5	4	1	0	0
6	13	2	7	4	0
5	8	2	5	1	0
4	5	1	3	1	0
3	3	0	3	0	0

PATIENTS STILL IN HOSPITAL

Months without treatment	No of cases	Cerebrospinal fluid				Relapses
		Normal	0–20 cells per c mm	20–30 cells per c mm	Above 30 cells per cmm.	
7	8	0	4	0	4	4
6	5	0	0	0	5	2
5	10	2	3	1	4	2
4	2	0	0	1	1	2
3	2	0	1	0	1	0

The 10 relapses in 27 cases had an average clinical duration of ten days There have been no deaths

Relapses

Relapses have been mild, and in only 2 cases did meningeal signs reappear All the others were indefinite febrile illnesses with inflammatory changes in the C S F These relapses responded very well to further treatment

This raises the question of preventive treatment in all cases where the cerebrospinal fluid does not rapidly return to normal and where, four months after the completion of initial treatment, the cell count is higher than 20 Indeed, in order to be doubly sure it would perhaps be advisable for all patients to undergo a second treatment The doses, in adults that we have begun to use in an attempt to prevent relapses are 20 g of streptomycin (1 g daily), 100 mg of isoniazid by mouth in the morning 100–150 mg of isoniazid intravenously at midday, and another 100 mg by mouth at night From our experience we can confirm the effectiveness o routine

SUMMARY

A combination of intramuscular streptomycin a
*oral and intrathecal isoniazid has been used in the treat*ment of tuberculous meningitis There have been deaths in 100 cases treated in this way Of the patients who recovered, only 7 showed significant sequelæ, none of them involving serious disability There have been 10 relapses, all mild and responding promptly to further treatment

C S.F.-ISONIAZID LEVELS IN TUBERCULOUS MENINGITIS

A P FLETCHER
M.D Lond, M R C P

SENIOR MEDICAL REGISTRAR, WRIGHT FLEMING INSTITUTE
MICROBIOLOGY, ST MARY'S HOSPITAL, LONDON

THE *ultimate test of any antibiotic or chemotherapeutic* régime is that of clinical trial, however preliminary observations on the concentration of antibiotic chemotherapeutic substances in various body fluids helpful in planning therapy Elmendorf et al have shown that isoniazid penetrates well into the cerebrospinal fluid (C S F) of patients with active arrested tuberculous meningitis, but the data inadequate to decide the correct dosage

The C S F -isoniazid levels found in 15 adult patients aged 16–41, with tuberculous meningitis are reported here These levels were repeatedly determined in patients throughout the course of the disease, while they were being treated with alternating high and dosages of isoniazid Present information suggests a dose of 10 mg of isoniazid per kg of body weight twenty-four hours is the highest that is likely to suitable for routine clinical use, and this level selected for the high dosage The Medical Research Council (1953a) showed that a dose of 200 mg spread over twenty-four hours regardless of body weight virtually non-toxic to patients and clinically effective pulmonary tuberculosis of adults This dose was selected for the low dosage The total 24-hour dose was administered half in the morning and half in the evening patients on the higher dosage received two or three times as much isoniazid as when they were on the lower dosage

Methods

Methods for the determination of isoniazid in body fluids are as yet imperfect To reduce error three methods were used in this investigation

(1) *Biological method* —Specimens were assayed with *Mycobacterium tuberculosis* H37Rv (human strains) as the test organism and with the media and precautions described by Medical Research Council (1948) The presence or absence growth was determined after fourteen days' incubation 37°C, specimens being assayed in duplicate, and standards run in triplicate

(2) *Method of Kelly and Poet (1952)* —The extraction an iso amyl alcohol-ether-ammonium sulphate system cribed for urine and plasma was found to be unsatisfactory when applied to C S F Specimens of C S.F, after protein precipitation with trichloracetic acid, were treated *p* dimethylaminobenzaldehyde reagent, and the resulting colour was estimated in a Spekker absorptiometer 2 cm cells and an Ilford 601 filter

(3) *Method of Cuthbertson et al (1953)* —The extraction into a butanol ether ammonium sulphate system had def advantages over the extraction procedure of Kelly and However, experiments in this laboratory showed that method of extraction did not give consistent results C S F in that with C S F containing known amounts isoniazid the extraction rate varied between 55% and relatively less material being extracted at higher concentrations Since the amount of interfering substances in C S F is less than in plasma, C.S F was directly treated

oryl chloride after protein precipitation with acid sodium ngstate. The resulting colour was read with a Spekker sorptiometer using 4 cm. cells and an Ilford 603 filter.

ERROR OF METHODS

) *Biological*

Although the biological method of assay has obvious mitations, in an investigation such as this, where the nemical methods are relatively non-specific biological ssay provides an essential check against the possibility estimating a biologically inactive metabolic derivative isoniazid.

hemical Methods

Effect of C.S.F.—Known quantities of isoniazid were ssolved respectively in water and in C.S.F. to give ncentrations ranging from 0·5 to 4·0 µg per ml and oniazid determinations were made on the specimens y both chemical methods. It was found that the alues for isoniazid were lower when the material was ssolved in C.S.F. rather than in water. The error due this cause varied from 5% to 15%. Triple determina ons were made on each specimen at each concentration y both methods; the greatest deviation from the mean ading was 10% while the average deviation from the ean reading was under 4%.

Effect of blank values.—C.S.F. after deproteinisation ves a high blank value when treated with either of the agents in question. Three separate determinations of ank values were obtained from each patient by stopping oniazid seventy two hours before the determination. ach blank value was used to correct the reading of e C.S.F. isoniazid level in specimens taken before or ter the blank determinations. The blank values by the eryl-chloride method were 0·9–2·3 µg of isoniazid per l of C.S.F. and by the *p*-dimethylaminobenzaldehyde ethod 0·5–2·0 µg of isoniazid per ml of C.S.F. The fferences between the three individual determinations r blank picryl-chloride values ranged from 0·1 to 9 µg of isoniazid per ml of C.S.F., average 0·3 µg per l.; and for the *p*-dimethylaminobenzaldehyde method om 0·1 to 0·8 µg per ml, average 0·4 µg per ml. Thus e question of the correct blank value was a matter of me uncertainty and a source of error which did not ceed ± 0·5 µg of isoniazid per ml of C.S.F. and was ely to have been about ± 0·2 µg per ml.

DIFFICULTIES WITH METHODS

Different batches of picryl chloride caused the develop nt of the reaction colour to proceed at different eeds. In most cases the development of the full colour s obtained immediately but in some cases the colour ok some hours of standing to develop.* As a routine bes were read at 2 and 12 hours to obviate this ficulty.

Certain batches of *p*-dimethylaminobenzaldehyde ected with C.S.F. in the cold. All C.S.F. in which a ld reaction colour was found was discarded, since the ferential analysis suggested by Kelly and Poet was und to be unsatisfactory.

p-aminosalicylic acid (P.A.S.) interferes with both actions, and no patient was treated with P.A.S. Both ethods were unaffected by the presence of strepto ycin in the usual concentration, but the *p*-dimethyl inobenzaldehyde reagent reacted strongly with pro ne. Piperocaine hydrochloride was used as a local æsthetic for all lumbar punctures.

Results

To ascertain whether the methods were in agreement terminations were made by all three methods on urteen specimens of C.S.F. (streptomycin had been opped seventy two hours previously to allow the biological method to be used). The biological method gave values averaging 1·8 (range 0·5–4·0) µg of isoniazid per ml of C.S.F., the picryl chloride method values averaging 1·5 (range 0·8–3·2) µg per ml and the *p*-dimethylaminobenzaldehyde method values averaging 2·2 (range 1·0–4·5) µg per ml. The '*t*' test of signifi cance showed $P > 0·1$. These figures suggested that the methods were in reasonable agreement, and that the chemical methods measured biologically active isoniazid. Further comparison between the *p*-dimethylaminobenz aldehyde and the picryl-chloride methods showed that the former gave results about 20% higher than the latter gave but when the results were tested statisti cally the difference was not significant owing to scatter.

TABLE I—RISES IN C.S.F. ISONIAZID LEVELS AT VARIOUS TIMES AFTER DOSE

Time after dose (hr.)	1–2	4–6	10–12	24
C.S.F. isoniazid level (µg per ml.) on daily dosage of 10 mg. per kg. of body-weight 12 hourly	1·4 (0·6–3·0)	3·6 (1·2–5·3)	0·6 (Detectable—1·8)	7/10 (Detectable)
C.S.F. isoniazid level (µg per ml.) on daily dosage of 200 mg. regardless of body-weight 12 hourly	1·0 (Detectable—2·8)	2·8 (1·0–3·6)	0·4 (Detectable—1·2)	4/10 (Detectable)

Each observation is the average of six readings (range in parentheses). Detectable = < 0·5 µg per ml.

Specimens of lumbar C.S.F. were withdrawn from patients 1–12 hours after a dose of isoniazid. Readings after 24 hours were taken after omitting one dose. So that the patients should not be subjected to more than the one lumbar puncture a day necessary for treatment curves showing the concentration of isoniazid at various times after a dose were constructed from samples on different days. Since there was a wide variation in the levels for any given patient, each of the points in table I was constructed from an average of six determinations on different patients, the ranges being shown in parentheses.

Table I shows that, after the oral administration of isoniazid a rise in the C.S.F. isoniazid level was apparent within 1 or 2 hours, the peak being reached within 4–6 hours. (Data confirming the peak at 4–6 hours are not given in table I, because there were only three readings at 7–9 hours.) The C.S.F. isoniazid level had fallen considerably 10–12 hours after ingestion of the dose but at the end of 24 hours isoniazid was still detectable in some patients.

Table II shows the total number of determinations done 1–12 hours after a dose. The results show a wide scatter as would be expected on the basis of the data in table I and because some of the patients being acutely ill with tuberculous meningitis, had troublesome vomiting. Patients who vomited after a dose of isoniazid were not given another dose because the purpose of table II was to show the C.S.F. isoniazid levels found in clinical practice. Analysis of the levels obtained when

TABLE II—NUMBER OF DETERMINATIONS MADE 1–12 HOURS AFTER DOSE OF ISONIAZID

C.S.F.-isoniazid level (µg. per ml.)	Not detected	0·0–0·49	0·5–0·99	1·0–1·49	1·5–1·99	2·0–2·49	2·5–2·99	3·0–3·99	4·0–4·99	5·0–6·50

On dosage of 200 mg. daily	—	4	3	3	7	1	1	5	—	1

---

* uthbertson et al. (1953) now believe that the full colour intensity will always develop immediately provided that the picryl chloride reagent is purified by double recrystallisation from chloroform.

the patients were acutely ill and less acutely ill (excluding patients who vomited) showed no striking differences, but patients with arrested tuberculous meningitis tended to show lower levels than did those with acute tuberculous meningitis (difference not statistically significant—$P > 0·1$)

Discussion

Analysis of the data in table II shows that there was a highly significant statistical difference between the C.S.F.-isoniazid levels obtained with the two dosages These were higher ($P < 0·001$) when the higher dosage of 10 mg per kg of body-weight was given (for most patients this dosage was two or three times the amount given on the low dosage)

The 14 day inhibitory C.S.F. isoniazid level for H37Rv is 0·06 µg per ml, and it is rather generally accepted that most of the "isoniazid sensitive" bacilli will be inhibited by a C.S.F. isoniazid level 0·2 µg per ml (Medical Research Council 1953b)

Mackaness and Smith (1952) and Suter (1952) have shown independently by macrophage culture that, whereas the ratio of the inhibitory level of streptomycin for free tubercle bacilli to its inhibitory level for intracellular tubercle bacilli is 1 : 20–80, that of isoniazid is 1 : 1 This demonstration that the action of isoniazid is unimpaired when the tubercle bacilli are intracellular suggests that in-vitro tests with isoniazid may have considerable relevance to clinical treatment The action of isoniazid on the tubercle bacillus is bacteriostatic rather than bactericidal, and probably little purpose is served by having very high levels of circulating isoniazid

This contention is supported by the findings of Barclay et al. (1953) with isoniazid rendered radioactive with C^{14} in the carboxyl position These workers showed that isoniazid levels higher than the lowest inhibitory level did not lead to a greater uptake of the isoniazid by the bacilli, and that reduction of the surrounding isoniazid level caused only a slow decrease of radioactivity in the bacterial cell Isoniazid-resistant bacilli took up only minute quantities of isoniazid at all levels These findings suggest that intermittent rather than continuous bacteriostatic levels of isoniazid may suffice for optimal therapy It is realised that high C.S.F. isoniazid levels do not necessarily either imply similar levels in the extracellular spaces of the brain or indicate high therapeutic activity

Data given earlier show that if isoniazid is estimated in the presence of C.S.F., the values obtained are about 10% too low Table II has not been altered to allow for this error, since the uncertainty about the blank value makes it inadvisable to apply a correction Probably, after all allowances have been made for technical errors, levels of 0·5–0·99 µg of isoniazid per ml of C.S.F. or more in table II represent entirely adequate bacteriostatic levels of isoniazid Since some of the readings in table II were made after the patients had vomited, and since this table incorporates estimations made twelve hours after a dose of isoniazid, the figures represent a conservative estimate of the C.S.F.-isoniazid levels likely to be obtained

The 12 patients treated with 10 mg of isoniazid per kg of body-weight daily showed no evidence of toxicity due to this dosage for 4–8 weeks

Table II shows that a dosage of 200 mg daily in adults regardless of body-weight gives rise to C.S.F.-isoniazid levels that appear on theoretical grounds to be desirable, though the adequacy of this dose can only be established by clinical trial

Debré and Brissaud (1952) have suggested that isoniazid should be administered both orally and intrathecally in tuberculous meningitis The findings in the present investigation suggest that intrathecal isoniazid

Summary

The C.S.F.-isoniazid levels were estimated in 15 with tuberculous meningitis in all stages of the The patients received alternating high and low of isoniazid

The two chemical methods used were checked a biological method to show that the chemical measured active isoniazid and not an inert metab derivative

Adequate bacteriostatic C.S.F. isoniazid levels found on both dosages throughout the illness

I wish to thank Dr W F J Cuthbertson, of the Gl Research Laboratories, and Dr S W A. Kuper, of Brompton Hospital, for providing me with details of picryl chloride method for the determination of isoniazi and Mr J Tobar for technical assistance in the laboratory

ANÆMIA ASSOCIATED WITH HÆMOPHILUS INFLUENZÆ MENING

D JOAN SCHIAVONE
MEDICAL STUDENT

SYDNEY D RUBBO
M B Melb, Ph.D Lond, Dip Bact
PROFESSOR OF BACTERIOLOGY
UNIVERSITY OF MELBOURNE

IN a survey of 1069 histories of acute meningit infants and children admitted to the Children's H Melbourne (Rubbo et al), our attention was draw the extensive use of blood-transfusions in *Hæmo influenzæ* meningitis This observation led to examination of the frequency and severity of in this disease and in meningococcal meningitis. T results are presented here

Investigation

It is generally recognised that 50–60% of an infants and children are secondary to infection (1947, Diamond 1950), but significant anæmia has usually been observed in acute infections of less th month's duration (Cartwright and Wintrobe 1952) finding of a frequent association of anæmia with infl meningitis clearly shows that this complication may

TABLE I—STANDARDS USED FOR CLASSIFYING DEGREE ANÆMIA IN CHILDREN

Age group	Normal Hb level (g per 100 ml)	Degree of anæmia		
		Mild < 85% of normal (g per 100 ml.)	Moderate < 75% of normal (g per 100 ml)	Severe < 65% (g. per 100
0–3 mos	15 (*104%*)	11·9 (*82%*)	10·5 (*72%*)	9·1 (

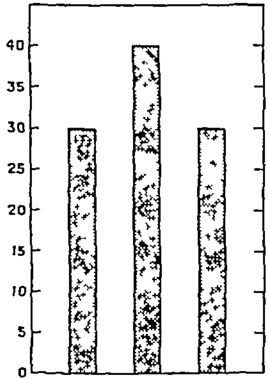
TABLE II—ANÆMIA IN ACUTE MENINGITIS IN CHILDREN

Ætiology	No. of cases	No. of cases with anæmia	Cases given blood transfusion (%)
influenzæ	196	89 (45·4%)	37·7*
meningitidis	141	11 (7·8%)	1·3

ncludes 11 cases given blood transfusions but not included in anæmic group because Hb estimations were not recorded

served in acute, as well as in chronic infections. Apart om isolated statements such as that of Turner (1948) io reported that 7 of her 40 cases of *H. influenzæ* eningitis required blood transfusion, the association of æmia with influenzal meningitis seems to have escaped tention. We report here the results of a study of 208 cteriologically proven cases of *H. influenzæ* meningitis, which 196 were consecutive cases admitted to the ildren's Hospital in 1946–52. For comparison, we fer to a series of 141 cases of meningococcal meningitis eated in the same hospital over the same period.

It was appreciated at the outset of this study that any timate of the frequency of anæmia would depend on the emoglobin level chosen as the criterion of anæmia. e level chosen was 85% of the expected normal level ter correction for the patient's age in the peripheral blood, 14·5 g. of hæmoglobin per 100 ml. of blood being taken as equivalent to 100% hæmoglobin. The hæmoglobin levels for assessing the degree of anæmia in various age groups are shown in table I.



g 1—Severity of anæmia in 89 cases of *H. influenzæ* meningitis.

Results

With this classification 89 of the 196 consecutive patients with *H. influenzæ* meningitis (45%) were anæmic on admission to hospital or developed anæmia within seven days of admission. This surprisingly high icidence is probably a conservative estimate for it does ot include 14 patients who received blood transfusions r the many patients given oral iron therapy who were ot classifiable because hæmoglobin estimations were not corded. In contrast the incidence of associated anæmia meningococcal meningitis was 7·8%. These differences able II) suggest that anæmia of meningitis may be eculiar to *H. influenzæ* infection.

As regards the severity of this anæmia, fig. 1 shows at in 70% of the anæmic patients the anæmia was oderate or severe—i.e., the concentration of hæmo obin was less than 75% and 65% of the corrected normal alue respectively. In some cases the anæmia was well elow these critical values and in 10% (18 patients) the emoglobin was equal to or less than 7·3 g. per 100 ml. g. 2).

Thus, anæmia in *H. influenzæ* meningitis is not only equent but also moderately severe. From the clinical andpoint it can be easily corrected and, if recognised, does not appear to affect the prognosis, particularly ith the modern chemotherapeutic control of the meningitis. In 1946–52 the over-all case-fatality rates among anæmic and non-anæmic patients were 14·3% and 13·2% respectively.

The mechanisms causing anæmia during infection fall broadly into three main groups—aplasia of hæmopoietic tissue, intravascular hæmolysis, and maturation arrest in the synthesis of hæmoglobin (Saifi and Vaughan 1944). We cannot offer any experimental evidence of its significance in *H. influenzæ* infection, but the following observations are relevant.

There appears to be a definite relation between the degree of anæmia and the severity of the infection measured by the concentration of glucose in the cerebrospinal fluid (C.S.F.) (Alexander 1943). This relation is brought out in table III, which shows that anæmia was present in 57% of all severe infections (C.S.F. glucose level below 10 mg. per 100 ml.), in 40% of moderate infections, and in 30% of mild cases.

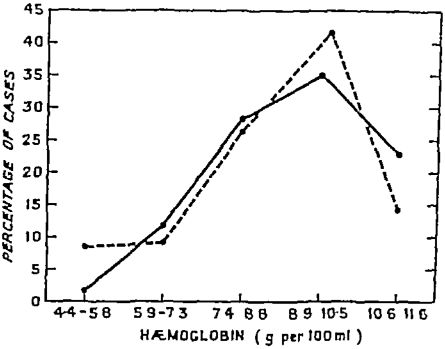


Fig. 2—Effect of serum therapy on degree of anæmia in *H. influenzæ* meningitis: solid line, 54 cases without serum therapy; interrupted line, 35 cases with serum therapy.

That the age of the patient did not affect the frequency of the anæmia was shown by the almost identical age distribution of anæmic and non-anæmic patients: 69% of all the patients and 71% of the anæmic patients were aged less than 1 year.

The blood-group of the patient had no apparent influence on the incidence or degree of anæmia; for a normal distribution of blood-groups A, B, O, and AB and of the Rh factor was found among the anæmic patients.

It was impossible, with the information available, to determine whether an incipient anæmia of dietary or other origin preceded, or was aggravated by, the infection. Most of the patients came from the industrial (lower economic class) areas of the city, but the same social distribution applied to cases of meningococcal meningitis in which anæmia was uncommon.

The question was raised whether the administration of type-b rabbit antiserum might be causally related to the development of anæmia. That this was not so is shown in fig. 2, in which the degree of anæmia in two groups of

TABLE III—RELATION BETWEEN DEGREE OF ANÆMIA AND SEVERITY OF INFECTION IN H. INFLUENZÆ MENINGITIS

Degree of infection	C.S.F. sugar level (mg. per 100 ml.)	No. of cases	Association with anæmia (%)				
			None	Mild	Moderate	Severe	All grades
Severe	< 10	76	43	17	16	24	57
Moderate	10–30	30	60	17	23	0	40
Mild	30–50	24	80	8	4	8	36

anæmic patients, one group treated with the antiserum (usually intramuscular) and the other not, showed much the same distribution Thus there was no evidence that serum therapy induced hæmolysis or agglutination, thereby increasing the severity or precipitating the anæmic syndrome

Discussion

We have been able to show that anæmia is often associated with *H influenzæ* meningitis but seldom with meningococcal meningitis (table II) This finding is of some interest in so far as many hæmatologists consider that significant anæmia is not seen in acute infections of short duration The frequency of the association in 196 consecutive cases was 45%, after the exclusion of those patients whose hæmoglobin levels were not recorded but who were treated by either blood transfusion or iron therapy A conservative estimate would be that half of the cases present with anæmia or develop anæmia during the illness, and in 70% of these the anæmia is moderate or severe (fig 1) In the present series two-thirds of the anæmic patients (38% of all the patients) were given blood-transfusion (table II) Whereas the severity of the anæmia was partly influenced by the severity of the infection (table III), age, blood-group, social class, and antiserum therapy (fig 2) did not affect the incidence or the severity

The question whether the anæmia was a predisposing cause or the result of specific infection is entirely open We noted that the anæmia often developed during the course of the illness, and not infrequently the hæmoglobin level rapidly fell in twenty-four to forty eight hours These sudden changes seem to indicate that mechanisms involving intravascular hæmolysis are at work during infection Unfortunately no complete observations on pigment balance were recorded in the histories A tentative suggestion is that sensitisation of the cells by *H influenzæ* polysaccharide (Keogh et al 1947) might lead to subsequent hæmolysis by a naturally occurring lytic component (e g , complement) or by chemotherapeutic agents in circulation (e g , sulphonamides)

Summary

An analysis of 196 consecutive cases of *H influenzæ* meningitis in infants and children revealed that 45% had an associated anæmia, and in 70% of these the anæmia was moderate or severe In contrast, the incidence of an associated anæmia in 141 cases of meningococcal meningitis was only 8%

The anæmia was more frequently associated with the severer forms of meningitis but was not related to the patient's age, blood group, or social class, or caused by the administration of type b rabbit antiserum

From a clinical point of view this association with anæmia should always be considered in the management of *H influenzæ* meningitis The anæmia did not affect the fatality rate, probably because it was recognised and treated (two thirds of the anæmia patients were given blood transfusions)

Possible mechanisms and the significance of anæmia in *H influenzæ* meningitis are briefly discussed

Our thanks are due to Miss A. A. Robbins, of the records office of the Children's Hospital, Melbourne, for her coöperation, to Dr V L Collins, medical director, for giving us access to case histories, to our colleague Miss Patricia Gladwell, and to the Medical Research Funds for a grant to one of us (D J S)

LACTOSURIA AND GLYCOSURIA IN PREGNANCY AND THE PUERPERIUM

F V Flynn
M D Lond

Christine Harper
B Sc Lond

P de Mayo
M Sc Lond , A R I C

From the Department of Clinical Pathology, University Col
Hospital, London

The application of paper partition chromatograp (Consden et al 1944) to the identification of sugars i urine, first described by Horrocks and Manning (194 marked an important advance in clinical chemistr Conventional methods of identification of urinar reducing substances by yeast fermentation and osazo formation are notoriously insensitive in practice an often yield equivocal results Paper partition chro graphy enables reducing substances to be identified certainty even when present in low concentration, the presence of more than one sugar may be shown by single test

With the introduction of this technique in our labor tory lactosuria was found to be very common in pr nancy, being more common than glycosuria Since th finding was at variance with current views, it was th desirable to reinvestigate the occurrence of lactosur and glycosuria in pregnancy

The frequent occurrence of glycosuria during pregnan is generally recognised , indeed its appearance after dose of glucose was at one time suggested as a diagnos test for pregnancy (Welz and Van Nest 1923, Hirst a Long 1926) Lactosuria has been known to occur dur lactation since Hofmeister (1877–78) first isolated lacto from urine, but most of the standard textbooks of clin chemistry emphasise the rarity of lactosuria befo delivery (Bodansky and Bodansky 1952, Cantarow a Trumper 1949, Duncan 1947, Harrison 1947) Hard et al (1947), however, state that lactose is found in th urine in pregnancy, and Peters and Van Slyke (194 mention that it is not uncommon to find traces of l in the later months of pregnancy

Reference to the earlier reports about lactosuria befo delivery shows lack of agreement

Lemaire (1895–96) identified lactose in the urine dur lactation by osazone formation, but before parturition could only detect glucose

Porcher and Commandeur (1904) identified lactose in th urine of a few women both before and after delivery

Williams and Wills (1928), using the osazone metho found no lactosuria before delivery in 21 clinically norm pregnancies in which sugar was present in the urine

Watkins (1928) claimed to have shown that small quantit of lactose were constantly present in the urine during th last stages of pregnancy, and that its excretion was sudde increased just before delivery , however, he did not identi the sugar but assumed that increase of the non fermentabl reducing substance represented lactose

Winter (1931), who recognised lactose by increased reducti after controlled hydrolysis as well as by the optical rotati and melting point of the isolated sugar, found only glucos in the urine before parturition and only lactose after deliver

Brock and Hubbard (1935) used a method of great sensiti and specificity to estimate the urinary sugars, determin the reducing power colorimetrically after differential bacteri fermentation , they showed lactose to be present in sma amounts in a large proportion of pregnant women, even in the early months

Archer and Haram (1948), using Fearon's methylam test found not a single positive test for lactose in 777 a specimens of urine from 123 patients, although lactose w found in the urine of 86 of 97 postnatal patients

Odin and Werner (1950), using paper chromatograph demonstrated lactose in the urine of 9 of 10 pregnant wome (Zilliacus and Roos 1952), also using paper chromatograph found lactose in the urine of 21 of 83 pregnant women, in case as early as 3 months

Clinical Data

ntrol Patients

Single specimens of urine were obtained from 372 selected patients, 240 non pregnant females and 132 ales, to act as controls Most of these specimens were om inpatients and outpatients attending University llege Hospital, but a few were obtained from healthy ung adults The age-distribution of these patients and e time of voiding the specimens were not standardised

ntenatal Patients

Specimens of urine were obtained from 245 patients tending the antenatal clinic of the hospital These tients were unselected in that they were booked nsecutively in the antenatal department, an undue oportion of primigravidæ is included because these e given priority for admission Specimens were obtained om each patient at every attendance at the clinic—i e rmally at the first attendance and then at monthly tervals until 32 weeks fortnightly between 32 and 36 eeks and thereafter weekly No specimens were tained before the 8th week of pregnancy Usually erefore, 12 specimens were expected from each patient . practice the full quota was not always obtained cause of either non-attendance at the clinic or failure to llect the specimens Specimens from patients attending e morning and afternoon clinics were voided between and 10 30 A.M and between 1 and 2 30 P.M respec vely The following details were abstracted from the tients antenatal notes date of last menstrual period e number of previous pregnancies, number of live rths, and whether the patient had diabetes mellitus any form of pregnancy toxæmia. The duration of egnancy was calculated from the first day of the last enstrual period In only a few instances were these lculations corrected when clinically this date was nsidered to be a month out

stnatal Patients

Clean specimens of urine were obtained from the tients followed antenatally on the second fourth and ghth days after delivery while in hospital and later at weeks and at any subsequent attendances at the stnatal clinic The former specimens were voided out 6 A.M and the latter between 1 and 3 P.M

Methods

Every specimen of urine had its specific gravity termined and was submitted to a qualitative Benedict st and to chromatographic analysis. While awaiting romatography it was stored at 4°C

ecific Gravity

This was measured with specific-gravity beads, the me set being used for all the determinations

alitative Benedict Test

This was performed and assessed in a standard manner follows:

Exactly 0 5 ml of urine and 5·0 ml of Benedict s qualitative agent (Benedict 1908–09) were pipetted into test tubes and ixed by shaking The rack holding the tubes was lowered to a boiling water bath for 5 minutes. On removal any red ange yellow or obvious green reductions were recorded as ch. Green reductions were subdivided into green 2 and green according to whether the colour was a yellowish green or a uish green. Thereafter the tubes were allowed to stand until dimentation was complete The precipitate was then amined in those tubes as yet ungraded; if there was none if it was grey the test was recorded as blue (or negative) hereas if any yellow component was present reduction was corded as green 1 With this technique the sensitivity of e test was such that glucose and lactose added to urine hich had previously not reduced Benedict s reagent could be tected in concentrations as low as 10 and 15 mg per 100 ml spectively

Chromatography

The general technique of Horrocks and Manning (1949) was followed with some modifications

As a routine 20 µl. of urine was spotted on the strips of filter paper; occasionally 40 µl or more was applied when the urine was unusually dilute Since absolute temperature control could not be achieved, marker strips spotted with known sugars were run at the same time to establish the R_f values under the prevailing conditions Normally the 4 : 1 : 5 n butanol acetic acid water solvent of Partridge and Westall (1948) was used but since this solvent does not separate lactose from maltose and glucose from galactose one or two specimens of urine from each patient were also run with the collidine lutidine-water solvent used by Dent (1948) for amino acid chromatography The latter solvent separates these pairs of sugars widely but, since the colour of the sugar spots is not so intense 80 µl of urine was applied to the strips developed with this solvent Immediately after develop ment of the colour the quantity of the sugar present was estimated by visual matching of the spots with standard charts. These permanent colour charts, one for lactose and one for glucose were constructed by carefully matching spots obtained on standard chromatograms. The accuracy of this method of estimation was determined by running 200 strip chromatograms spotted with a complete range of sugar concentrations it was shown that 75% were correctly assessed to within ±33% of the actual value of the colour standard

The spray reagent used to show up the reducing sugars on the chromatograms is prepared by dissolving 1·25 g of *p* phenylene-diamine and 3·0 g of stannous chloride in 200 ml of ethyl alcohol and 50 ml of glacial acetic acid. After standing for half an hour the reagent is filtered Normally it was used three hours after preparation but it will remain stable at room temperature for two or three days. The incorporation of stannous chloride delays the appearance on the paper of a background colour which develops after the paper has been heated or exposed to light. After the freshly sprayed chromatogram has been heated in an air oven at 105°C for 15 minutes hexoses show up as brown spots and glucuronates and pentoses as red spots; urates do not react. The intensity of the colour reaction with this reagent is such that lactose and glucose can be detected in concentrations of 17 and 14 mg per 100 ml respectively when 20 µl of the solution is applied to the chromatogram run with the n butanol-acetic acid water solvent

Analysis of Results

The clinical and laboratory data were analysed with the aid of punch cards. The urinary findings were grouped as indicated in the accompanying tables and figures Where more than one specimen of urine from a given patient was examined in a particular period—e g 34–35 weeks inclusive—the results were averaged before transference to the cards. Since 24-hour specimens of urine were not available, the quantitative sugar values were corrected for the variable dilution factor of the specimens by referring the figures to an arbitrary standard specific gravity of 1·020 Thus a urine of sp gr 1·010 assessed as containing 150 mg of lactose per 100 ml would on correction be assigned a concentration of lactose of 300 mg per 100 ml.

Results

Results of Benedict Tests

The over-all results are given in table I which shows that the frequency of urines giving positive reduction tests in pregnancy is about 2½ times and in postpartum patients about 3 times that in the controls They also indicate that it is only in the puerperium that the incidence of the heavier reductions of Benedict s solution is much increased

The results of the Benedict tests at different stages of pregnancy and the puerperium are further analysed in fig 1 It will be noted that the percentage of specimens giving no reduction falls from about 40% at 8–11 weeks to about 21% at 40 weeks. The other notable change is the increase in the incidence of the heavier reductions which begins at about 28–31 weeks and persists until

TABLE I—OVER ALL RESULTS OF BENEDICT TESTS

Source of urine	No of specimens tested	Percentage of negative Benedict tests	Percentage of positive Benedict tests		
			G_1	G_2	Ye & Or
Female controls	240	71 3	25 4	3 3	
Male controls	132	64 4	31 1	4 5	
Antenatal patients*	2373	27 1	68 5	3 9	0 5
Postnatal patients*	657	12 2	69 2	17 7	0 9

* The findings in one patient, shown subsequently to be mildly diabetic are not included

delivery On the second day of the puerperium there is a slight increase in the incidence of reductions, by the fourth day only 2 4% of specimens show no reduction and 35% show heavy reductions Six weeks after delivery 10% still show a green-2 reduction

Chromatography Results

The over all results are shown in table II The collidine lutidine runs showed that in no case was maltose or galactose present in those urines examined

It will be noted from table II that about 9% of the controls, both male and female, had detectable quantities of lactose in their urine, and that lactosuria was found at no less than 50% of the antenatal patient attendances, the frequency of lactosuria being double that of glycosuria The other notable finding is the remarkably low incidence of glycosuria after delivery, an incidence even lower than that found in the controls

The chromatography results in the pregnant women are further analysed in fig 2 These results show that

(1) The incidence of lactosuria increases steadily from the third month of pregnancy until 34–35 weeks, when 64% of the patients show lactosuria Thereafter there appears to be no significant change

(2) Lactosuria is more common after delivery, 99% of patients having detectable quantities of lactose four days after delivery

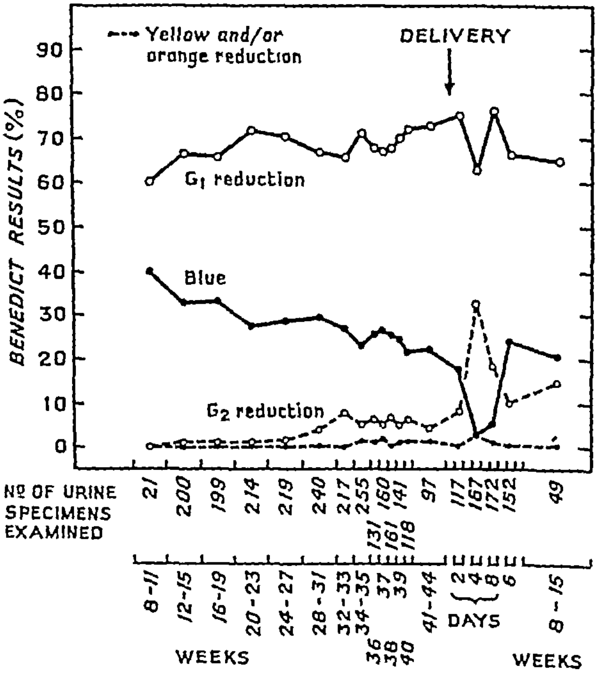

Fig 1—Results of Benedict tests at different stages of pregnancy and puerperium Blue = no reduction

(3) The amount of lactose excreted is usually less t 100 mg per 100 ml before delivery and more than 100 mg 100 ml during the early puerperium

(4) The incidence of glycosuria rises sharply after the month and fluctuates between 20% and 31% for the remai of the pregnancy

(5) The glycosuria of pregnancy disappears abruptly delivery, no urinary glucose being found on the eighth after delivery or thereafter

(6) The quantity of glucose excreted during pregnancy usually less than 67 mg per 100 ml

(7) After 16–19 weeks' pregnancy lactosuria is m common than glycosuria

To discover the constancy or otherwise of lactose glucose excretion during pregnancy, the findings in patients from whom specimens were obtained at ten more of the antenatal attendance periods (weeks 41 counting only as one attendance period) were analys In only 8 (6%) of these patients did lactosuria no

TABLE II—OVER ALL RESULTS OF CHROMATOGRAPHIC ANALY

Source of urine	No of patient attendances	Percentage of patient attendances with lactosuria found (with or without glycosuria)	Percentage of patient attendances with glycosuria found (with or without lactosuria)*	[illegible]
Female controls	240	9 6	14 2	[illegible]
Male controls	132	8 3	15 9	[illegible]
Antenatal patients	2174	50 0	24 0	[illegible]
Postnatal patients	649	86 2	0 9	[illegible]

* The findings in one patient, shown subsequently to be diabetic, are not included

occur, whereas 42 (33%) never had glycosuria at time Lactosuria was found at every antenatal atten in 5 patients (4%) and glycosuria constantly in 3 pati (1 of these 3 patients was subsequently proved to mild diabetes mellitus) Of the 119 patients who show lactosuria, lactose was detected in 61 (51%) on six more occasions, whereas of the 85 who showed glycos in 42 of the patients (49%) the sugar was detected on one or two occasions In most of the patients, the fore, lactosuria and glycosuria occur as [illegible] phenomena

Investigation of Mechanism

In an attempt to elucidate the mechanism respons for lactosuria and glycosuria in pregnancy the incid of the excretion of lactose and glucose was compared groups of patients selected from the 127 from whom or more specimens had been obtained In every case groups compared consisted of the maximum of pa in whom the incidence of all but one of the foll variables was identical age group (under 20, 20- 25–29, 30–34, 35–39, 40 or more), number of prev abortions (0, 1, or 2), number of children (0, 1, 2, or m than 2), clinics attended (A M or P M.), occurrence toxæmia (no toxæmia, slight pre eclamptic toxæ definite pre eclamptic toxæmia, or essential hyp tension) The results are shown in tables III–VI "distribution correction" in these tables shows to wh extent the differences found are likely to be attribut to the groups not being exactly similar in terms numbers of specimens examined at particular periods pregnancy Thus, in table III part of the difference in over all incidence of lactosuria between the two groups due to the fact that 8 of the A M clinic patients atten at 8–11 weeks (when the expected incidence of lacto is only 9 5%) and 6 at 41–44 weeks (when the expe incidence of lactosuria is 53 2%), whereas only 1 of P M clinic patients attended at 8–11 weeks and 11 41–44 weeks fferences due to such inequalities are eliminated The rrection factors were calculated from a knowledge of) the numbers of patients providing specimens at rticular periods of pregnancy, and (2) the expected cidence of the sugar excretion at each particular riod (fig 2)

In table III the effect of the time of day on sugar cretion is shown It can be seen that the incidence of ycosuria, and to a lesser extent of lactosuria, is higher the patients attending the afternoon clinic

In table IV the effect of previous pregnancies is shown his table shows that the incidence of the excretion of oth sugars is lower in those who have borne children his finding was elaborated by *comparing the results in* ree groups of 10 patients with no children with one ild and with more than one child. The results con med the above mentioned finding and suggested that e incidence of lactosuria diminishes with increasing mbers of successful pregnancies, the corrected per ntage *of patient attendances with lactosuria being* 3·0 50 5 and 31 7 respectively

In table V the effect of age is shown From these data seems that age has no effect on the incidence of lacto ria, but that the frequency of glycosuria probably creases with age

In table VI a comparison is made between a group of 4 patients with toxæmia and a similar group of 44 *ithout any form of pregnancy toxæmia Of the patients* ith toxæmia 4 had definite pre-eclamptic toxæmia requiring admission to hospital, 4 had essential hypertension, and the remaining 36 had only a slight degree of pre-eclamptic toxæmia as defined by Browne (1947) *The results show that there is no connection between* the milder varieties of toxæmia and sugar excretion in pregnancy

TABLE III—COMPARISON OF SUGAR EXCRETIONS IN PATIENTS ATTENDING MORNING AND AFTERNOON ANTENATAL CLINICS

—	Patients attending		Distribution correction for P.M clinic group
	A.M. clinic	P.M. clinic	
No of patients in group	24	24	
No of patient attendances	262	267	
Percentage of patient attendances with lactosuria	42 7	51·4	−1 7
Percentage of patient attendances with *glycosuria*	14 1	25 8	+0 4

It is well known that postnatal lactosuria and lactation are related but it was noted that lactose excretion occurred quite frequently in mothers not feeding their infants. Because of this we compared the incidence of lactosuria in breast feeders and in non breast feeders *The results are shown in fig 3, the number of patients* concerned being shown in table VII The small number of non breast-feeders makes comparison of the two groups unsatisfactory However it seems that the incidence of lactosuria up to eight days after delivery is comparable in the two groups although lower concentrations of lactose were found in the urine of the non breast-feeders The incidence of lactosuria six weeks after delivery is about three times as great in breast-feeders

Discussion

Results of Benedict Tests

The results recorded here confirm the well established fact that the concentration of urinary reducing substances is often increased in pregnancy and the puerperium However the incidence of urine giving positive Benedict tests is considerably in excess of that recorded by other workers in the controls and antenatal and postnatal *groups* (*Williams and Wills 1928* Richardson and Bitter 1932 Brock and Hubbard 1935 Weidin 1948) The results obtained by Archer and Haram (1948) are nearest akin to ours they found reduction by 64% of 777 specimens of antenatal urine 81% of 258 speci mens of postnatal urine, and 11% of 503 control specimens of urine The discrepancies are probably due *to differences in technique Precise* measurement of the urine and reagent, use of a boiling water bath for 5 minutes and standing the tubes until sedimentation is complete are particularly important if small quantities of reducing substances are not to be missed The importance of technique is shown by the differing opinions on the sensitivity of the test; Watkins (1928) found that urine with more than 150 mg of sugar per 100 ml usually gave a positive test, whereas Brock and Hubbard (1935) and Weidin (1948) found that all urine with 60 mg or more of glucose per 100 ml. gave positive tests. Most textbooks of biochemistry state that the test will detect glucose down to a concentration of 100 mg per 100 ml. We were surprised to find that we could detect lactose and glucose at much lower concentrations. In this connection it is significant that sugar was

Percentage of patient attendances with glycosuria	26 1	17 7	+0 1

* Of these patients 20 had 1 child 7 had 2 children, 1 had 3, and 1 had 6

recorded as having been detected at the clinic in only 2 of the antenatal specimens of urine , our findings on the same specimens were 1625 green-1 reductions and 104 green 2 or heavier reductions At the clinic urine is tested for sugar by the Benedict test, but the quantities are not measured precisely, the tube is heated over a bunsen flame, and the result is recorded immediately

The results of the Benedict tests show a progressive rise in the percentage of positive tests as pregnancy proceeds Richardson and Bitter (1932) and Weiden (1948) found a uniform incidence throughout, but they examined fewer specimens

Chromatography Results

The results of the chromatographic analyses confirm the findings of Brock and Hubbard (1935) that lactosuria occurs not only during lactation but also in a large proportion of pregnant, and a small number of non-pregnant, women Our results also establish that lactosuria occurs in a few men taking a normal diet Lactosuria has previously been reported as occurring in men after ingestion of 10 g or more of pure lactose (Folin and Berglund 1922, Watkins 1928, Winter 1931), but the methods of identification were not entirely satisfactory

As indicated earlier, the finding of many workers that lactosuria in antenatal patients occurs either not at all or only towards the closing stages of pregnancy can be attributed to the use of methods of sugar identification which are of insufficient delicacy As can be seen from fig 2, the concentration of lactose present was almost always less than 100 mg per 100 ml , and indeed in most cases it was so low as to be near the limit of sensitivity of the method—i e , about 20 mg per 100 ml In the controls also the amount of lactose was minimal

TABLE V—COMPARISON OF SUGAR EXCRETIONS IN DIFFERENT AGE GROUPS

—	Patients aged 20–29	Patients aged 30–39	Distribution correction for group aged 30–39
No of patients in group	25*	25†	
No of patient attendances	284	260	
Percentage of patient attendances with lactosuria	46 1	46 8	+0 1
Percentage of patient attendances with glycosuria	11 6	25 6	+1 3

* Of these patients 7 were aged 20–24 years and 18 were 25–29
† Of these patients 17 were aged 30–34 years and 8 were 35–39

The sensitive and specific method adopted by Brock and Hubbard (1935) is alone satisfactory for the purpose of comparing our lactose results with those obtained by others Their method enabled as little as 10 mg per 100 ml to be determined quantitatively with great accuracy They found lactose in concentrations of 10–13 mg per 100 ml in 3 of 24 specimens from non pregnant women, 20–99 mg per 100 ml in 21 of 42 antenatal specimens of urine, and 20–399 mg per 100 ml in 9 of 11 postnatal specimens of urine These r closely resemble our own The fact that we found la in 9% of controls, when our method cannot detect than 17 mg of lactose per 100 ml , could be due to examining a larger number of specimens, to the incl of patients outside the age limits of 18–45 years, an dietary differences In some cases we found h concentrations of lactose than did Brock and Hub (1935) , this is certainly partly explained by our cor tion of the quantitative figures to a specific grav 1 020, which is probably higher than average norm

Our figures relating the incidence of lactosuria duration of pregnancy and puerperium establish tha frequency of lactose excretion increases with durati pregnancy between 12 and 35 weeks, and confirm finding of Watkins (1928) that the amount of lac excreted after delivery often increases to reach a p about the fourth day The findings of Brock Hubbard (1935), that lactosuria may not be present in pregnancy and may persist long after delivery, are confirmed

Apart from our finding that glycosuria occurs al 1½ times as frequently during pregnancy as in cont our results concerning glucose excretion do not con so closely to those of Brock and Hubbard (1935) found glucose in concentrations over 14 mg per 100 in 9 of 24 controls, in 32 of 42 antenatal specimen urine, and in 7 of 11 postnatal specimens of u Richardson and Bitter (1932), who used a fermenta method to detect glucose, also found this sugar l frequently , they found glucose in concentrations 14 mg per 100 ml in 31 of 50 antenatal speci urine and in 15 of 50 specimens of urine obtained o twelfth day after delivery The discrepancy betw our results and those of these American workers mu due to differences in diet In the case of the puerperal specimens of urine our finding so few case glycosuria is certainly partly explained by our obta these specimens while the patients were fasting confirm that glycosuria occurring early in pregnancy not always persist until term, a view originally forward by Williams and Wills (1928) but not substantiated by Richardson and Bitter (1932) or Weiden (

TABLE VI—COMPARISON OF SUGAR EXCRETIONS IN PATI WITH AND WITHOUT TOXÆMIA

Relation of Benedict Results to Chromatography Findi

The significance of a positive Benedict test i considerable import to both patient and clinician T is no doubt that even strongly positive tests during puerperium may be normal and are due almost ex sively to lactose Unfortunately it is difficult to deter to what extent positive tests during pregnancy are to lactose or glucose, since glucuronate was f extremely often, with or without these sugars, occasionally fructose and pentoses were also fo Comparison of figs 1 and 2 certainly indicates tha the second half of pregnancy slight reductions are likely to be due to lactose than to glucose It ther seems that, where the Benedict test is made as descr above, slight reductions graded as green 1 may be considered as normal during pregnancy

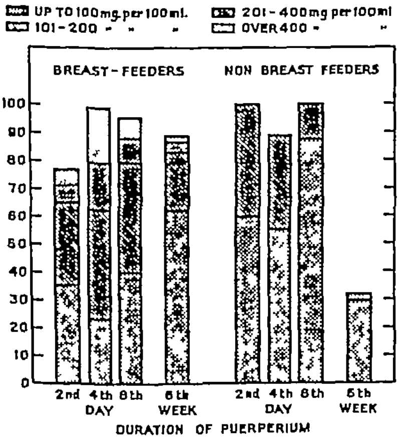
all these patients lactation was being suppressed with stilboestrol.

chanism of Production of Glycosuria and Lactosuria

here is abundant evidence that glycosuria during gnancy is at least partly explained by a lowering of renal threshold for glucose (Welz and Van Nest 1923 st 1925 Lawrence 1927, Williams and Wills 1928 iden 1948) Some workers maintain that a diminished ose tolerance also plays a part (Höst 1925 Williams Wills 1928), but more recently Weiden (1948) and kson (1952) have found that with few exceptions the od-sugar curve in uncomplicated pregnancy does not above normal limits Our finding that glycosuria more common among patients attending the after n clinic is compatible with these facts; thus, it is bably a reasonable assumption that patients attending the afternoon would have enjoyed a greater carbo rate intake just before their visit than those attending morning clinic The more frequent excretion of ose by patients in the older age group might be due glucose tolerance diminishing slightly with age; thus been demonstrated in males by Smith and Shock 49)

xcept during the puerperium there is less certainty ut the mechanism by which lactose comes to be reted in the urine There is good evidence that there o renal threshold for lactose (Winter 1932 Brock and bbard 1935) and it has been established by amputa of the udder in goats that breast tissue is the only rce of lactose during the puerperium (Porcher 1904) ollows that lactosuria must result either from synthesis actose in the mammary glands or from absorption of ose from the gut without prior splitting into glucose galactose The occurrence of spontaneous lactosuria h equal frequency in male and female control patients suggests that in these patients the source of the sugar is the gut. The experiments of Watkins (1928) and Winter (1931) with oral administration of lactose suggest that lactosuria may arise in this way Since lactosuria occurs much more often during pregnancy it is unlikely to be alimentary in origin at that time unless one postulates either a diminished lactase activity or alternatively a greatly augmented milk intake Pregnant women in this country are given a free pint of milk which contains 26 g of lactose but this extra milk is unlikely to explain spontaneous lactosuria since Watkins (1928) has shown that tolerance to oral lactose during pregnancy is two or three times greater than normal On the other hand the progressive development and secretory activity of the breasts during pregnancy could explain the frequent occurrence of lactosuria and its greater incidence in the later months. On balance a mammary origin seems more likely Our finding that lactosuria occurred slightly more often in patients attending the afternoon clinic might indicate a diurnal variation in lactose synthesis The finding that lactosuria occurs less often in multiparæ is interesting it could be explained on the basis that their breasts having previously undergone complete development can more readily accommodate the small volume of secretion without the pressure rising within the alveoli leading to reabsorption of lactose Thus Watkins (1928) postulated that lactosuria during lactation resulted from milk production exceeding milk removal The fact that we often found lactosuria in those in whom lactation was being suppressed supports this hypothesis



3—Incidence of lactosuria in breast-feeders and in non-breast-eders. The number of patients providing specimens is shown in ble vII.

Summary

The excretion of sugars in the urine during pregnancy and the puerperium has been reinvestigated by paper partition chromatography Results are presented of both qualitative Benedict tests and chromatographic analyses on single specimens of urine from 372 control patients and on 2373 antenatal and 657 postnatal specimens of urine from 245 pregnant women

With a critical technique a very high incidence of Benedict reductions was found during pregnancy (72 9%) and after delivery (87 8%) Where this test is done carefully reduction during pregnancy is often due to lactose

Lactosuria occurs in male as well as non pregnant female patients on normal diet. Lactose usually traces was detected in the urine of 9% of controls of either sex; this is probably alimentary in origin.

Lactosuria is common during pregnancy, occurring about twice as often as glycosuria Lactose usually in small amounts was found at 51% of all antenatal attendances being detected at some time in 94% of patients attending the clinic regularly Glucose was found at 24% of antenatal attendances but 33% of regular attenders never excreted detectable quantities of it

Antenatal lactosuria increases in incidence as pregnancy advances was found more often in the afternoon and more commonly in primigravidæ

Antenatal glycosuria was found more often in the afternoon and more frequently in older patients.

The frequent excretion of considerable quantities of lactose during the puerperium is confirmed and pregnancy glycosuria was found to disappear rapidly after delivery

In pregnancy glycosuria is probably due to a low renal threshold for glucose, and lactosuria to escape of lactose formed in the mammary glands

Glucuronate was found very often in the antenatal specimens of urine and traces of pentoses and fructose were found in a few cases.

A new spray reagent for showing up sugars on paper chromatograms is described.

We thank Prof W C W Nixon for permitting us to obtain urine from the obstetric patients and for giving us access to their clinical records, the nurses in the Obstetric Hospital for their great help with the collection of the urine, Mr V K Asta for the standard colour charts and the diagrams, and Miss D Bryant for technical assistance Work included here was done during the tenure by one of us (P de M) of a grant from the Rockefeller Research Fund of University College Hospital Medical School

IMPALEMENT OF THE RECTUM

L P Thomas
B Sc, M B Wales, F R C S
SENIOR SURGICAL REGISTRAR, ROYAL INFIRMARY, CARDIFF

Injury of the rectum is relatively uncommon in civilian life, and the published reports are of small series of individual cases and collective reviews These deal mainly with impalement injuries caused by the patient falling or sitting on an upright article, the configuration of the thighs and buttocks causing the instrument in many cases to enter the anus

Van Hook (1896), reviewing the published cases, pointed out that the injury occurred in males in 75% of cases, falling on to a pitch-fork being the common mode of injury Habbegger (1912) reported a mortality of 26 8% in 179 cases, rising to 78 5% when the peritoneal cavity and abdominal viscera were involved This indicates that the lesion is potentially serious, but the use of antibiotics has greatly improved the prognosis

Types of Injury

There are two main varieties in the first the offending object enters the anal canal directly, in the second it enters the rectum after passing through the buttock or the perineum When it enters the anal canal directly, the laceration of the rectum is commonly situated on the anterior wall 2 or 3 in from the anus The extent of the injury naturally depends on the force of penetration It may be a superficial laceration of the rectal mucosa, or it may penetrate the bowel wall and enter the pelvic cellular tissue or reach the peritoneal cavity or the bladder There may be no outward evidence of the injury on examination of the anal region, and this may cause some delay in the diagnosis of a rectal wound

The injury of the buttock opens up the ischior fossa, a fat containing space particularly liable infection An abscess forms in the loose parar tissues quickly and may be overlooked In this situa rapid resolution is unusual and may lead to the format of chronic abscesses or to fistulæ Seybold et al. (19 reporting seven cases seen in the Mayo Clinic betw 1910 and 1939, point out that only one patient wa hospital for less than thirty days, the remainder b detained longer because of infection The preventi such infection should be possible with early diagn and adequate treatment

Injury of the perineum may include laceration of urethra, here again early treatment will avoid ser complications and later development of a stricture.

Diagnosis

Examination of the patients in the more serious inju reveals usually only a slight degree of shock, the they may be in considerable pain

Local examination of buttock and perineum may s slight bruising of the anus if the article has entered t anal canal Lacerations of the buttock will be evid and should be inspected in a good light, and an atter should be made to determine the direction of entr the offending article Digital examination of the rect may not always reveal a wound of the rectal wall, t only indication of this may be blood on the exa finger

Abdominal examination in cases of peritoneal penet tion will show lower abdominal tenderness and mu guarding in the early stages Later, well-marked rig will develop and the bowel sounds will usually absent

The *urine* should be examined at the earliest opp tunity, the patient being catheterised if unable to p urine normally The presence of blood indicates d to the bladder, cystoscopy would then be indicated determine the site and extent of the damage

Proctoscopy is essential and will reveal the lacera *in most cases* The mild *case* will *only* show bruising the rectal wall, penetration into the peritoneal cav cannot be diagnosed with certainty by this examinat Sigmoidoscopy with the introduction of air is con indicated

Radiography—The abdomen should be X rayed every case Involvement of the pararectal tissues c be shown by the presence of air outside the rectal w Peritoneal penetration will be shown by the presence a small amount of air under the diaphragm in the e position Dilatation of loops of the small intestine, d to the early onset of peritonitis, will be present in ab six hours Free fluid between bowel loops will be ev in the later stages of peritonitis

Treatment

Shock will be treated in the usual manner, but morph should be withheld until a definite decision has been m regarding peritoneal involvement

Wounds of the buttock should be fully explored u general anæsthesia and surgical toilet done The wou are left open and allowed to granulate

A wound of the perineum is explored, special attent being paid to the urethra Damage to this struct should be repaired by suture over a catheter possible Suprapubic drainage of the bladder is th indicated

Laparotomy is indicated in all cases of perito involvement, and should be done in any doubtful c Even in early cases well-marked hyperæmia of the bo wall and thin purulent exudate are found With t patient in the Trendelenburg position the small intes is lifted out of the pelvis and examined for lacerat The wound in the rectum is next exposed and su-layers. Drainage of the pelvis, through the lower end the incision, is necessary James (1940) makes no empt to suture the rectal wall but covers the laceration th a peritoneal flap It is considered safer to suture e rectum if possible, to prevent continued infection of e pararectal tissues. The bladder is next examined; a wound is found it should be repaired with two layers sutures and suprapubic drainage should be instituted *e remainder of the bowel is next inspected for tears* tention should be given to the mesentery for any scular injuries a slowly developing hæmatoma should dealt with because it may later devitalise an area of wel. James (1940) reports a complete tear of the mesen ry of the sigmoid colon but this did not require resection the bowel Laceration of the duodenum has been ported on one occasion. The presence of retained reign bodies should be investigated.

Colostomy is indicated in the following circumstances) a large laceration of the rectum which is difficult to ose (2) a wound involving the rectum and buttock, an endeavour to lessen the infection in this region; d (3) severe damage involving rectum and bladder e colostomy can be closed when the rectal and buttock ounds are healed. This takes from three to six weeks cording to the severity of the injury

The patient should receive antitetanic and anti gas ngrene serum Phthalylsulphathiazole 10 g daily is ven by the mouth Penicillin or aureomycin in adequate ses is also given If peritonitis is well developed travenous fluid should be given and gastric suction arted early to combat paralytic ileus.

Case-reports

Case 1 —A schoolboy aged 14 was admitted to Bridgend eneral Hospital at 12.30 P.M on May 2 1950 An hour fore admission while jumping over cricket stumps in the aying field he fell and a stump entered his anus through s trousers He complained of severe spasmodic suprapubic in and nausea. He passed a bloodstained stool but could t pass urine

Examination showed pallor, slight cyanosis, pulse rate 108 d temperature 98 8°F Generalised abdominal rigidity was esent with much tenderness in the lower quadrants. The adder was not palpable The anus had a small abrasion teriorly with some blood coming from the rectum.

At operation three hours after injury proctoscopy showed perforating wound 1 in. long on the anterior wall of the ctum and about 2 in. from the anus. The rectum was cleaned t and a tube inserted Cystoscopy showed a normal bladder parotomy revealed early peritonitis with a retroperitoneal ematoma on the left side of the pelvis. There was a wound in. long in the rectum just above the peritoneal reflexion his was sutured and covered with peritoneum A small ceration of the pelvic mesocolon was found and repaired A ainage tube was inserted in the pelvis. A left inguinal loop lostomy was done

Progress —On May 4 a mild paralytic ileus developed and as treated with intravenous fluids and by gastric suction roctoscopy on May 23 showed that the laceration had not ealed but complete healing had taken place by June 15 hen the colostomy was closed. The boy was discharged home June 29 when bowel action was normal

Case 2.—A man, aged 20 was admitted to Bridgend General ospital at 10 30 A M on June 2 1950 after falling 20 ft. om a ladder on to a wooden fence He was complaining of in in the buttocks His general condition was fair with ly slight shock.

Examination revealed an irregular laceration 3 in long on e left buttock about 3 in from the anus. Rectal examination vealed a laceration of the lateral wall of the rectum about /2 in from the anus. Abdominal examination showed no gidity or tenderness. Catheterisation produced 10 oz. of ormal urine Four hours later the patient complained of wer abdominal pain and examination showed lower abdo-inal tenderness and rigidity

At operation six hours after the injury the buttock wound as explored and excised Proctoscopy confirmed the laceration previously described and no damage to the sphincter muscles was seen no further lesion was found in the rectum Laparotomy revealed pelvic peritonitis with bloodstained purulent exudate A small laceration in the rectum found above the peritoneal reflexion was sutured; this laceration had not been found on proctoscopy Slight bruising of the pelvic colon and a small laceration of its mesentery were found No injury to the bladder was found A left inguinal loop colostomy was done and the pelvis was drained.

Progress—The patient received antitetanic anti gas-gangrene serum, penicillin, and sulphadiazine He developed mild paralytic ileus On July 18 proctoscopy showed the buttock wound, which was not healed, to be still communicating with the rectum This was healed by Aug 24 and the colostomy was closed on Aug 28 The patient was discharged home on Sept. 12, all wounds having healed. He was re-examined in six weeks and again two years later when he was symptom free There was a moderate amount of scarring in the buttock, and slight scarring was palpable in the rectum.

Case 3 —A boy aged 6 years, was admitted to the Cardiff Royal Infirmary on Aug 31 1952 after having fallen backwards on to a bamboo cane which pierced his trousers and entered his anus He vomited two hours later and complained of central abdominal pain. His bowels had acted twice before admission and the stool contained blood He passed urine normally

On examination his general condition was good slight abdominal tenderness was present, and bowel sounds were normal. Rectal examination revealed no laceration, no blood being present on the examining finger Slight bruising of the anal margin was present Radiography of the abdomen revealed no abnormality

Progress —The boy had a bowel action next day when a little blood was present. The abdominal pain and tenderness had gone. On Sept 2 a small lump was palpable in the anterior wall of the rectum. Proctoscopy on Sept 5 revealed a $^1/_2$ in. laceration of the anterior wall of the rectum 2 in. from the anus, with a slough in the base Bimanual palpation discovered an inflammatory mass about 1 in. in diameter anterior to the rectum The patient was treated with chloramphenicol and sulphathalidine Proctoscopy on Sept 17 showed that the laceration had now healed and the mass had disappeared He was discharged home on the following day Follow up examinations have shown the healing to be complete

Discussion

The main lesson to be learnt from these cases is that early treatment is essential in limiting infection Full examination and special investigations are necessary to determine the exact nature of the injury In case 2 where no abdominal tenderness was found on first examination radiography would probably have shown intraperitoneal gas and enabled the diagnosis of peritoneal penetration to have been made earlier In case 3 there did not appear to have been any peritoneal damage, though the patient complained of abdominal pain

It is essential in these cases to know whether the rectum is perforated and if so whether the peritoneum is involved

Colostomy is discussed by most workers and many do not advocate it strongly; but it seems advisable in most cases, even though it prolongs the period spent in hospital and entails a further operation for its closure (Powers and O'Meara *1939*, Siler and Bebb *1950*) Even with modern chemotherapy it was considered safer to do colostomy in two of these cases In the second case with perforation of the rectum through the buttock, it was essential to prevent spread of sepsis and later formation of fistulæ.

I am indebted to Dr Jeffery Jones Mr A. C. Lysaght, and Prof A. G Watkins for permission to publish these cases, and to Mr D J Harries for help in the preparation of this report

EXERCISE TESTS DURING TREATMENT OF HYPERTENSION WITH HEXAMETHONIUM

VAGN RØNNOV-JESSEN
M D Copenhagen
ASSISTANT PHYSICIAN
From the Medical Department of the Frederiksborg County Central Hospital, Hillerød, Denmark

In the course of treatment of hypertension with hexamethonium I have observed that a few patients have appreciable subjective symptoms despite the fact that they have been given an apparently adequate dosage leading to a proper reduction of their blood-pressure in the upright position Such patients feel well at rest and when they walk about quietly, but feel dizzy on slight exertion and have to stand still, sit down, or even lie down

One explanation might be that, in these patients, hexamethonium did not prevent a considerable rise in blood pressure on exertion, but it was striking that the symptoms might also appear in patients who had not been troubled, before treatment, by pronounced symptoms of hypertension caused by exercise

It therefore occurred to me that the symptoms determined by exercise in such patients might be due to a fall in the blood pressure under treatment with hexamethonium during exercise, instead of the usual rise

Hitherto only a few reports have been published on blood-pressure during exercise under treatment with hexamethonium Hood et al (1952) state that under these conditions there is considerably less rise in the blood pressure than usual, but so far as I know a fall in the blood-pressure determined by exercise in the course of treatment with hexamethonium has not yet been reported

Investigation

I investigated the effects of exercise on patients treated with hexamethonium The procedure followed in these investigations, which were made with Krogh's bicycle ergometer, and the results of the investigations will be described in detail elsewhere Here mention will only be made of the importance of the exercise tests in finding the proper dosage of hexamethonium

The blood-pressure is measured with the patient erect, and a combined oral and hypodermic administration of hexamethonium, or of hexamethonium in polyvinyl pyrrolidone with the longer-lasting effect, has been used (Smirk 1952, Ronnov-Jessen and Bech 1953, Ronnov Jessen 1953) Exercise tests will be required only in the cases in which the adjustment of the patient to the dose is beset with the difficulties mentioned above

Illustrative Case-records

Case 1 —A fisherman, aged 57, had an attack of violent hypertensive encephalopathy, since when he had had increasing dyspnœa on exertion for a couple of months For this reason he could walk only about 50 yards at a time when admitted

Treatment —Since his condition remained unchanged after a fortnight's stay in hospital and he was still hypertensive, treatment with hexamethonium was begun

Progress —During the next few months his condition improved considerably, and he could ride a bicycle 3–6 miles without being tired [illegible] the day his systolic blood pressure was 110–150 mm Hg in the u posture, and his general health was excellent Afte months' treatment he began to complain of dizzines oppression in the precordial area, even on moderate exe These symptoms were most pronounced during the first hours following the injections The blood pressure in upright posture had remained unchanged and satisfa

Exercise tests with Krogh's bicycle ergometer (fig 1) sh that, with a blood pressure of about 145/110 mm. Hg the patient sitting (corresponding to 125/95 mm. Hg in upright posture), the blood pressure fell considerably a sense of epigastric oppression developed when the exe amounted to 360 kilogramme metres (kg.m) per minute 2 minutes With an intensity of 540 kg.m per minute 1½ minutes the patient became pale and felt unwell dizzy, with precordial oppression and a fall in the blo pressure to 110/70 mm. Hg With a blood pressur 160/110 mm Hg with the patient sitting (correspon about 140/100 mm Hg in the upright posture) the fall much lower, and the patient had no complaints An at was therefore made to maintain a systolic blood pressur 140–160 mm Hg in the upright posture During the t weeks since then the patient has been feeling better and been much less troubled by his condition

Case 2 —A farmer, aged 55, with severe hyperten albuminuria, and pronounced retinal changes, had been a few months completely unfit for work, with severe att of hypertensive encephalopathy, dyspnœa on exertion, a attacks of stenocardia

Treatment and Progress —Hexamethonium therapy duced considerable subjective improvement and got rid of headache and dizziness, and the patient was feeling well a blood pressure of 150/100–200/120 mm Hg in the up posture compared to the former pressure of about 2 mm Hg When he was allowed to go for walks outside precincts of the hospital, however, he began to complain dizziness and general malaise when he walked rather quic especially during the first few hours after an injection.

Exercise tests (fig 2) showed that he could intensity of exercise of 540 kg m per minute for 2 minutes minute after a minute's rest without being troubled and a resulting moderate fall in the blood pressure when original pressure was about 200/120 mm Hg, but he collapsed doing the same amount of exercise when the blood pressure was about 180/105 mm Hg In this pat who had the same blood pressure in the sitting and upright postures, we therefore tried to keep the sy blood pressure 190–200 mm Hg During the twelve w since then the patient has been feeling well, though he is somewhat dizzy on too great exertion.

Discussion

The fall in the blood-pressure on exertion in th patients is presumably due to the effect of hexamethon

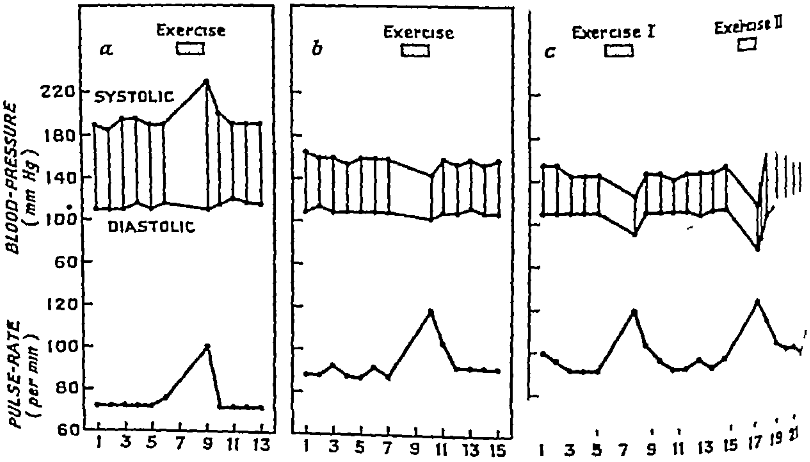

Fig 1—Changes in blood-pressure of case 1 during exercise (360 kg m per min for 2 min) a methonium in last 24 hr and patient had no complaint other than slight precordial b, 2 hr after hexamethonium bromide 100 mg in 25% polyvinylpyrrolidone hypodermically had no complaint after exercise c 1 hr after similar injection patient had precordial op after exercise 360 kg m per min for 2 min (I), and became pale and complained of dizziness, ma and precordial oppression after exercise 540 kg m. per min for 1½ min (II)

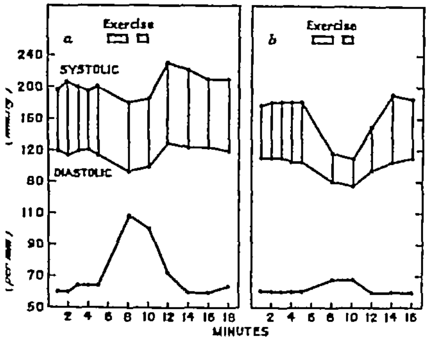

2—Changes in blood-pressure of case 2 during exercise (540 kg.m. er min. for 2 min. + 1 min. after a minute s rest) : a, 7 hr after podermic injection of hexamethonium bromide 230 mg in 25% olyvinylpyrrolidone patient had no complaint apart from fatigue legs after exercise; b 2 hr after similar injection patient became ale, felt dizzy and unwell and nearly collapsed.

the sympathetic, preventing the depletion of the blood pots in the course of exercise when the dose adminis ed is too large This means, in other words that there failure of the inflow into the right ventricle It appears case 2 (fig 2b) that there was only a slight increase in pulse rate during exercise when the effect of hexa thonium was vigorous whereas there was a normal rease in the pulse rate when the effect of hexameth ium was less pronounced (fig 2a) This is presumably e to the fact that in case 2 hexamethonium produced very effective block of the sympathetic nerves to the art. Generally a less pronounced blocking effect on the mpathetic nerves to the heart is seen

The importance of these observations is as follows

1) When the blood pressure in the course of treatment with xamethonium falls below a certain level some patients w during exercise an additional fall in the blood pressure h resulting hypotensive symptoms and presumably a risk thrombosis in the brain and the heart.

2) Patients like case 2 can presumably be protected to ne degree against stress on the circulation during exercise n though the reduction of the blood pressure obtained at t is rather slight There can hardly be any doubt that some es in which treatment has been abandoned have been of same type as case 2 These patients had such severe nplaints after a fairly slight reduction of blood pressure it it was wrongly believed that treatment would be of no

Conclusion

The exercise tests have shown that some patients whose od pressure had fallen to a reasonable level during atment with hexamethonium had an additional fall blood pressure during exercise with resulting hypo sive symptoms Such patients should have their od pressure adjusted so far as possible at a suitable her level, so that it fluctuates only slightly during ercise

In the treatment of hypertension with hexamethonium nerally the ideal would be to adjust the blood pressure that it shows only slight fluctuations during exercise. ere are presumably only a few patients in whom this incompatible with a more considerable reduction of blood pressure towards the normal in the upright sture

Summary

In most hypertensives the reduction of the blood ssure towards the normal in the upright posture is mpatible with only small fluctuations of blood essure during exercise but in some patients treated with hexamethonium the blood pressure falls considerably during exercise, with resulting hypotensive symptoms

By means of exercise tests these patients can have their blood pressure adjusted to a level which allows them to exercise without any appreciable fall in the blood pressure

A few patients treated with hexamethonium develop symptoms of hypotension during exercise even though the blood pressure in the upright posture has been only comparatively slightly reduced. If this is recognised and a somewhat slighter reduction than usual is therefore attempted these patients may nevertheless be beneficially treated with hexamethonium

Messrs May & Baker Ltd supplied the hexamethonium compounds.

RESPIRATION PUMP FOR POLIOMYELITIS

W Ritchie Russell
C B E M.D Edin F R C.P., F.R C P.E.
CLINICAL LECTURER IN NEUROLOGY IN THE UNIVERSITY OF OXFORD

Edgar Schuster
O B.E., D Sc.

The use of positive pressure artificial respiration through a cuffed tracheotomy tube has been advocated by Lassen (1953) for some cases of poliomyelitis. The indications for using this method are not yet fully determined but it seems desirable that poliomyelitis units should be prepared to establish this type of artificial respiration when other methods prove inadequate

The machines described here have been designed to supply the air and/or oxygen required at any desired pressure, rate, and volume and have both been shown to operate satisfactorily for 4 weeks in a case of poliomyelitis in which there was extreme spinal and bulbar paralysis after this period natural respiration returned

It should of course be emphasised that, as Lassen pointed out, very careful supervision by anæsthetists is required for these cases whatever system may be used for delivering the necessary air or oxygen

The two pumps described here have these factors in common :

(1) The pressure under which air is delivered to the patient is obtained by weights pressing downwards on the top of the bellows or piston so that no accidental circumstance can increase the pressure beyond the maximum attributable to the weight selected

(2) The pressure can be varied by varying the weight

(3) The volume of air delivered at each stroke can be adjusted by controlling the length of travel of the piston or bellows top

(4) The respiration rate can be adjusted by altering the speed of the driving or regulating motors

Pump A (fig 1) is driven by an electric motor pump B (fig 2) by vacuum The suction system provided in the wards and theatres of this hospital provides a negative pressure of 10–20 in Hg and was found to be a convenient and satisfactory source of vacuum to operate pump B

PUMP A

The motive power and speed regulation are provided by a universal motor with a built-in rheostat and reduction gearing giving an output of 60–200 r p.m The rotation is transmitted by a pinion to a large gear wheel, the speed reduction being about 1 : 8 Thus the maximum respiration-rate is 25 per min , the minimum usable speed is about 14 per min The air movement is obtained by the 'Oxford' inflating bellows (Macintosh 1953) The large gear rotates about a horizontal axis, and about $^3/_4$ in from its face is a vertical slideway, the centre of the gear being in the same plane as the centre line of the slideway A slipper mounted on this is provided at its upper end with a projecting fork which engages with the handle of the bellows The slipper carries near its lower edge on one side a horizontal fin projecting towards the gear On the gear is a rubber-tyred roller mounted with the eccentricity needed to give the desired length of movement to the slipper As the gear rotates, the roller, when it leaves its lowest position and starts moving upwards and to the side, passes under the horizontal fin of the slipper and, as its movement is continued, carries the slipper upwards with it until it has moved so far to the centre line again as to disengage itself from the fin

In the original form of the pump the slipper was then free to move downwards by gravity driving the top of the bellows with it This was found to give too long a time interval between the end of inspiration and the beginning of expiration, because the expiratory valve at the patient's end of the air delivery tube did not open until the slipper had started to rise again This difficulty has been got over by holding the slipper at its highest position with a spring-loaded catch until the catch is thrown out of action by the roller in its downward path The weight of the slipper is enough to give an air-pressure of about 14 cm H_2O Additional weights placed on the top of the projecting fork can bring it up to more than 20 cm The volume of air delivered is regulated by a movable stop which limits the downward travel of the slipper

PUMP B

The body of the pump consists of a brass cylinder clamped between upper and lower end-plates The lower plate carries the delivery nozzle and the inlet tube and valve There is a side nozzle on the inlet tube with a stopcock for introducing oxygen when required

The cylinder contains a heavy brass piston carrying the conventional leather cup facing downwards It is guided by a rod passing through a bearing in the upper plate Above the bearing the rod passes through a collar, to which it is fixed by grub screws This c limits the downward motion of the piston and ser a rest on which additional weights can be placed movement of the piston is regulated by a rotating driven by an electric gramophone motor Its can be varied between 14 and 24 r p.m by using centrifugal governor of the motor The valve in a bronze body with two pairs of nozzles on the opening from internal ports in the bore (A1 and and B1 and B2) The ports of each pair are one immediately above the other The valve has a cut in it, which when it comes to a pair of ports connects them One of each pair of ports (A1 and is connected by its associated n a length of tubing to the upper of the cylinder, and the two rem ports (A2 and B2) are connected tively to the suction mechanism and free air Thus, when the recess is A1 and A2, air is sucked from the part of the cylinder and the piston till it reaches its limit, which is set b adjustable stop A gas tap regu the speed at which the piston can The recess occupies about 120° of circumference of the valve, and a time after it has passed over A1 and it starts to connect B1 and B2 this happens, the pressure in the up part of the cylinder returns to atmosph and the piston consequently falls, expel air from the delivery nozzle Its ra fall depends on the resistance met with the expelled air and its weight It s times happens, both with pump B with pump A, that the resistance is great to allow the piston or bellows to reach its lower limit in the time avail

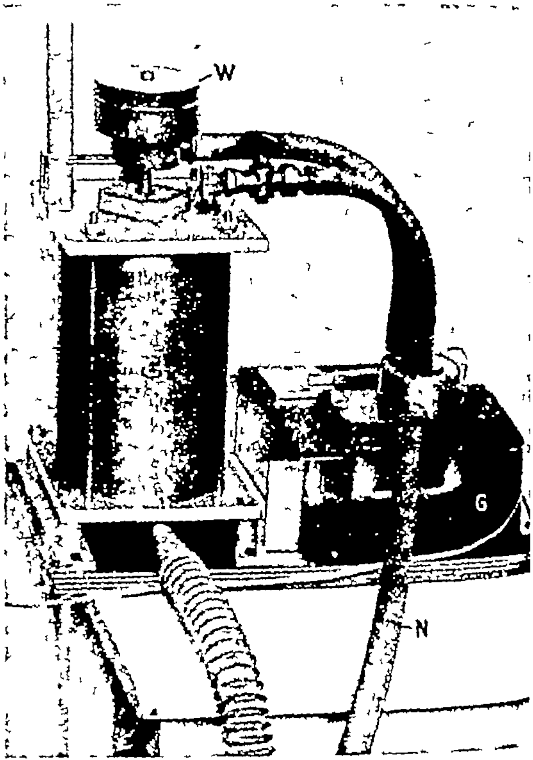

Fig 2—Pump B W, weight-operated piston in cylinder (C), delivery tube from hospital suction system ; G, gramophone operating valves.

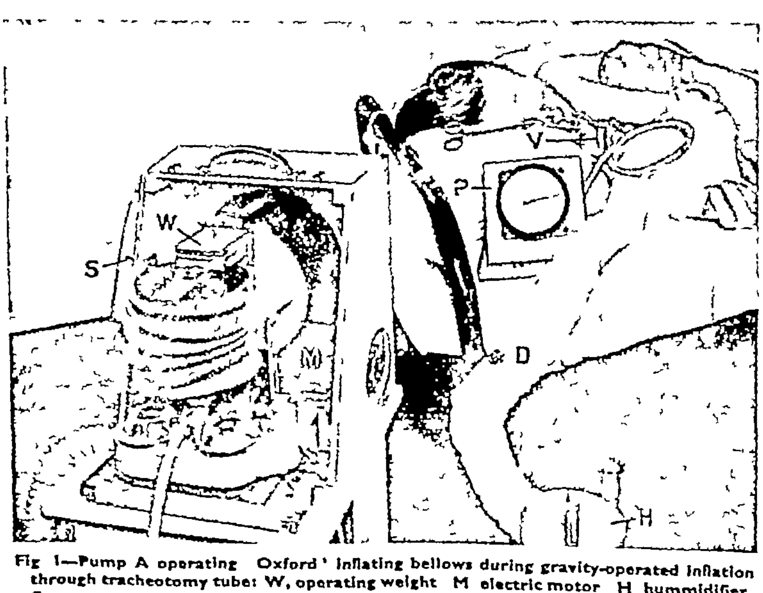

Fig 1—Pump A operating 'Oxford' inflating bellows during gravity-operated inflation through tracheotomy tube: W, operating weight M electric motor H hummidifier P pressure gauge ; D, lagged delivery tubing V, expiratory flutter valve (Stott) ; stop for volume control

is may be taken as a danger signal The exact position the piston and its actual range of motion are indicated a pointer attached to its rod which moves up and own a vertical scale rising from the upper plate whose ivisions represent amounts of 100 ml

A good method of controlling delivery of the appro riate proportion of oxygen and air by either of these umps is *provided by attaching an anæsthetic bag to* e air inlet and feeding into this bag the desired mixture f gases through an entrainment device

These initial designs, though capable of being improved, rovide a safe form of apparatus which is adjustable ot only for rate but also for pressure and volume

The pumps are manufactured with improvements by essrs H. G East & Co. Longworth Road Oxford and e named "Radcliffe Respiration Pumps A and B The xpiration valve used was the flutter valve designed by Dr D Stott and manufactured by Messrs. Owen Mumford, reen Place, Abingdon Road, Oxford With this in use the se of the expiratory valve on the inflating bellows must be moved. We are indebted especially to Dr A Crampton mith and Dr J M K. Spalding for supervising the use of ese machines

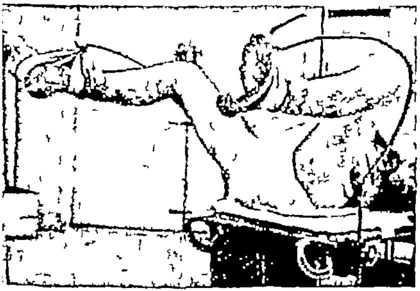
New Inventions

LEG SUPPORTS FOR CYSTOSCOPY AND PERURETHRAL RESECTION

In cystoscopy the position of the patient's legs is a tter of some importance; it affects both the comfort the patient and the convenience of the surgeon. It tters even more in perurethral resection and other doscopic operations. The leg supports should hold the s flexed not more acutely than a right angle and ould not come between the surgeon's head and the tient's thighs, thus allowing the fullest range of vement of the endoscope as in excavating the lateral es of the prostate or in catheterising an awkwardly uated ureteric orifice. The perineum should be flush th the end of the table and it is an advantage to have feet high enough to be out of the way A proper stoscopy table may meet all these requirements, but is not always convenient to use it in a theatre which is t devoted entirely to urological work.



The supports illustrated here hold the legs in the quired position They are a variant of the ordinary ithotomy supports and can be fitted to any standard eration table. They were made by the engineer's staff the hospital and are of stainless steel The iron protopes were in all important respects satisfactory but did t look smart enough to win general approval in the atre.

Reviews of Books

The Spinal Cord

A Ciba Foundation Symposium Editors: J L MALCOLM M.B., D.MED.SC; J A. B GRAY M.A M.B Editor for the Ciba Foundation: G E W WOSTENHOLME O.B.E., M A., M.B assisted by JESSIE S FREEMAN M.B., D.P.H. London: J & A Churchill 1953 *Pp* 300 30*s*

In introducing the discussions of which this publication is the printed record Prof G L. Brown indicated that the symposium had been limited to the spinal cord in order to avoid the danger that the members might find with them 'people whose language we could not understand We felt that if we stopped at the medulla oblongata everybody would understand everybody else' From this arbitrarily narrowed territory there is but a single geographical departure—a contribution by Lorente de No on the conduction of impulses on the neurones of the oculomotor nucleus It must not be imagined, however, that this volume is a simple account of the present state of knowledge of the function and structure of the spinal cord, a Rattiganesque 'Reflexes without Tears, for to this anatomically limited field have been applied all the special devices of the electrical, pharmacological and anatomical worlds Two of the early sections deal with the anatomical organisation of motor cells in the spinal cord of sheep and cats, but the motif in most of the contributions is biochemical or electrical. The contributors are internationally famous in neurophysiology: Eccles, Lorente de No Laporte, Skoglund Matthews Adrian, Liddell Whitteridge and Young—to mention only a few In spite of the complexity of the work reported the information contained in the articles and the points raised in the subsequent discussions are of great interest not only to neurophysiologists but to clinical researchers and clinicians in neurology generally The articles dealing with the effects of various drugs on monosynaptic and polysynaptic reflexes are particularly interesting in relation to recent attempts to relieve clinical spasticity The printing is clear and easily readable, and the diagrams well set out and understandable—respects in which this record of a symposium differs from some others

Fifty Years of Medicine

Lord HORDER G C V O, M.D F R.C.P London Duckworth. 1953 Pp 70 5*s*

This book is an expanded version of the three Harben lectures delivered in December 1952 at the Royal Institute of Public Health and Hygiene The first lecture entitled The Birth of Scientific Medicine describes the progress made by medicine during the last half century The second, Medicine Enlarges its Boundaries, discusses, among other things, nutrition, physical medicine, industrial medicine and nursing The third on The Present and the Future contains a full blooded attack on the National Health Service Act and the Minister responsible, and tackles the problems of noise smoke cremation and hygiene in time of war—problems on which the author has himself done a great deal to arouse and guide professional and public opinion. Whether one agrees or disagrees he is always interesting and frustrated medical men will get full value from the seven pages dealing with medicine and the State

Synovial Fluid Changes in Joint Disease

MARIAN W ROPES M.D., associate physician; WALTER BAUER, M.D., chief of medical services, Massachusetts General Hospital Boston Cambridge Mass.: Harvard University Press. London Oxford University Press 1953 Pp 150 25*s*

This is a first-class piece of work. The publisher's note calls it a distinguished definitive study of joint fluid in health and disease.' This is no exaggeration; it is a painstaking evaluation of the results of some 1500 specimens of synovial fluid in various diseases and is presented with obvious fairness. The authors have had the same difficulty as other workers in this field in obtaining normal synovial fluid to act as a basis for comparison but this is really an interim report on their studies, which extend back over the last twenty years, and there is admittedly still a great deal to discover

From their already massive data they have been able to divide joint disease into two major groups—a "traumatic" group (which includes degenerative arthritis osteochondritis dissecans, and Charcot's joints) and an "infectious" group (which includes rheumatoid arthritis and tuberculosis) By examination of the synovial fluid, these two groups can be fairly reliably differentiated With the knowledge they put at our disposal the diagnosis of the "observation knee" and other obscure effusions into joints is going to be facilitated Within the groups, the findings in each disease are admittedly not so helpful in diagnosis, though in many instances they can be strongly suggestive

This book, which is one for the specialist, expresses the results of a major piece of planned research There is no padding but so far as is possible with such concentrated material the facts are presented in a readable way

Diseases of the Ear, Nose and Throat

A Textbook of Clinical and Laboratory Procedures GEORGES PORTMANN, M D, professor of otorhinolaryngology, University of Bordeaux Baltimore Williams & Wilkins London Baillière, Tindall, & Cox 1951 Pp 728 £7 10*s*

Professor Portmann is a prolific author of books and contributor to journals The quantity of his published work is astonishing, but what is even more astonishing is its quality and diversity All these attributes are illustrated in this book, which appeared two years ago It comes as a surprise to learn that so many investigations of such different kinds are possible, but it would test the energies even of the author to use all of them, and most readers would welcome more critical guidance in their selection. As in all French textbooks the anatomical sections are particularly good, but the ear, nose, and throat specialist in this country rarely attempts also to be a radiologist, and the long descriptions with numerous illustrations of radiographic technique seem out of place Nevertheless, the better understanding of the methods employed, which a study of these descriptions will inevitably induce, must lead to an improvement in interpretation Tests of function of the cochlea and vestibular apparatus are exceptionally well described and illustrated, but again there is no reliable guidance on which tests to select The American translators have adequately conveyed the fluent and emphatic manner of the original

Functional and Surgical Anatomy of the Hand

EMANUEL B KAPLAN, M D, F.A C S, assistant professor of anatomy, Columbia University, New York Philadelphia and London. J B Lippincott 1953 Pp 288 80*s*

THIS scholarly work, written by a man who is both a practical anatomist and a practising orthopædic surgeon, is not intended to be encyclopædic Nevertheless the lymphatic system is the only aspect of the subject which is treated really briefly The illustrations—especially the diagrams demonstrating the action of the various muscles in movements of the fingers—are particularly good Much of the work is original, and in consequence the description of the mid-palmar fascia and the various septa attached to it differs from accepted teaching in several respects, being of special interest in connection with Dupuytren's contracture

A few tables might have been helpful, particularly in the listing of possible variations The wording is not always clear, and there are some minor errors—such as reference to the phalanx when the metacarpal is meant, and vice versa The index is good, and the value of the carefully chosen bibliography is greatly enhanced by the brief notes which the author has added under many of the more important listed works, calling attention to the special significance of each

The book can be highly commended to all interested in the subject.

Long-term Diabetes

KNUD LUNDBÆK, M D, Copenhagen, lecturer in internal medicine Aarhus University Copenhagen Ejnar Munksgaard 1953 Pp 197 Cr 32

THIS book is described on the title page as giving the clinical picture of diabetes mellitus of 15–25 years' duration, with a follow-up of a regional series of cases A [illegible] 165 living patients in the series were followed up, and information was obtained on the 69 who had by the time the series had been collected The pictur the incidence of complications and their correlat may therefore be considered reliable for this par Denmark, even though some of the information had be obtained retrospectively A number of interest points emerge Thus two-thirds of the diabetics 60–70 years had heart-disease, and diabetic retin was present in 77% In spite of this, only 3% of t series were disabled by poor eyesight, and the incide of retinopathy did not increase after 15 years' durat of diabetes The author also comes to the conclusion that there is nothing to suggest that catar is a long-term diabetic manifestation In discussing controversial question of the relation of diabetic cont to the incidence of complications, he feels safe in c cluding only that retinopathy was less common in th with good control, but the range of control in the does not appear to have been very extensive or easy decide The monograph is valuable not only for t detailed information it contains but for the review published work

Pitkin's Conduction Anesthesia (2nd ed Philadelp and London J B Lippincott 1953 Pp 1005 19 The American surgeon George Pitkin was a pioneer of l and block anæsthesia during the first part of this when the results of general anæsthesia were harder on patient than those of the surgery itself Conduction an thesia was his hobby, and he spent a great part of hi compiling notes and having illustrations made of suc techniques He died in 1943, three years before the edition of this volume—which is based in part on his o work—was published, and one year after the first paper written on the use of curare in clinical anæsthesia advent of the muscle relaxants has revolutionised ge anæsthesia to such an extent that the need for local or b methods has steadily diminished Good general anæst is now less exacting, and is usually followed by fewer comp tions, than are some forms of purely local anæsthesia there is a field of application for local techniques in diag and therapeutics

This book is the standard work of reference for all type local anæsthesia It is encyclopædic, containing des anatomy, pharmacology of drugs, full and liberally illustr descriptions of all techniques, and chapters on refrigera anæsthesia and on complications In this edition the ed (Dr James L Southworth, Prof Robert A. Hingson, Dr Winifred M. Pitkin) have successfully revised rearranged parts of the text to bring them up to date in light of recent knowledge Many new illustrations, an considerable amount of information concerning the co continuous extradural and segmental spinal anæsthe have been added

A Textbook of Medical Psychology (London Hog 1952 Pp 352 30*s*)—The tenth edition of Prof E Kretschmer's well known text (reviewed in THE LAN 1951, i, 894) appeared in 1950, with additions based on physiological research of W R Hess, and an expansion of section dealing with psychotherapy Dr E B Straus again rendered a service by providing a faithful transla which *is, on* the whole, clearer and more readable than original. The longer sentences are broken up, the abst nouns are made more concrete, and it is only rarely cloudy or compound terms, so easily accepted in Ger prove too much for him and he either invents a neolo such as "morphopoiesis," or takes refuge in literal transla Professor Kretschmer's disregard of work published languages other than German does not lessen the usefu of this book as a handy guide to large areas of Ger psychiatry, now rather regrettably neglected outside Germ

Guide to Human Parasitology for Medical **tioners** (5*th* ed London H K Lewis. 1953 Pp 25*s*)—Blacklock and Southwell's well known *Guide* maintained its popularity since the appearance of the fir edition in 1940 Now it has been brought up to date Prof T H Davey, and large sections of it, notably t malaria, have been rewritten in a clear, concise, and ac manner The three new coloured plates are all good, espec the one which depicts blood parasites in thick film prep tions, and draws attention forcibly to the most als artefacts This work remains unsurpassed in clarity judgment as a textbook for students and technicians, a groundwork for sincere practitioners of tropical medi

... Enter another case for CASILAN

He's five or six years the wrong side of sixty pays little attention to his diet makes do with 'tea-and toast' meals almost totally devoid of protein

Certainly he's a case for Casilan — for Casilan can give him all the protein he needs, without adding bulk to his diet or straining his digestion Indeed, every ounce *of Casilan provides him with more protein than four eggs* or a pint and a half of milk !

With almost every food or drink, Casilan mixes easily, unobtrusively *That is why it is so well accepted* not only by the aged but by everyone in need of extra protein — expectant and nursing mothers, for instance, and fast-growing children.

CASILAN Trade mark **Milk Protein Powder**

In 8-oz. cartons and in 40-oz. tins

A larger size is available for hospital kitchens.

Pleasant Antibiotic Therapy for all ages

The successful administration of Chloromycetin in the treatment of many bacterial, viral and rickettsial infections is vital. To overcome any difficulty that may be experienced, either with very young patients or those unable to swallow capsules, Suspension Chloromycetin Palmitate is available. This pleasantly flavoured preparation contains a tasteless derivative of Chloromycetin In this form it is easily taken by patients of every age and condition.

Each 4 c.c (teaspoonful) is therapeutically equivalent to 125 mg Chloromycetin Hydrolyses readily in gastro-intestinal tract yielding the pure antibiotic.

indicated in the treatment of

PERTUSSIS INFANTILE GASTRO-ENTERITIS

Mitral Stenosis

N the past few years much has been learnt about ral valve disease, but many problems are still olved The published results of mitral valvotomy encouraging with 60–80% of patients greatly proved but the mortality rate lies between 5% l 10%[1–3] The number of patients who die, or are improved, as a result of the operation might be *uced by better selection of cases Such selection* often difficult, since it is not always possible to dict whether a valve will be amenable to satis tory valvotomy, or whether other factors may vent a successful outcome

The great diagnostic difficulty is in detecting the ve which is incompetent as well as narrowed Pure greatly predominant, mitral incompetence can ially be detected readily enough by physical and liographic examination[4] but when mitral incompe- ice is associated with significant stenosis diagnosis y be much more difficult Any or all of the follow signs, in association with those of mitral stenosis uld arouse suspicion an apical systolic murmur of re than moderate (grade III) intensity, a soft first art sound and opening snap of the mitral valve, t ventricular enlargement, cardiographic signs of reased left ventricular dominance, and a very large t auricle on fluoroscopy The pulse is full,[2] rather an of small volume as in pure severe mitral stenosis ere are many further methods of assessing the degree mitral incompetence—notably observation of the m of the pulmonary capillary venous pulse by dging the cardiac catheter in a small branch of the lmonary artery[5 6] A large positive wave in ventri lar systole suggests incompetence[6 7] Although ere have been contrary reports,[8 9] *there is evidence* at the pulmonary capillary venous pulse reflects ssure changes in the left auricle[9 10], but a pattern nstant enough to be diagnostic of mitral incompe ice has not so far been agreed on, and similar curves y be found both with predominant mitral stenosis d with predominant mitral incompetence[11] The ophageal auricular pulse tracing and the electro- mogram have not proved helpful[12] while systolic pansion of the left auricle on fluoroscopy, although esent in pure incompetence[4] is also often seen in tral stenosis.[2 12] A loud systolic murmur at the ex *is probably the most important single sign of* tral incompetence[13] it may occasionally be sent in stenosis,[13] but in this event the first sound usually loud and the opening snap of the mitral valve clear[2] Careful clinical and radiological examination remains the most satisfactory method of diagnosing mitral incompetence Slight incompetence is no bar to operation, and may be reduced by successful valvotomy, but in the presence of pronounced incompetence valvotomy is useless Attempts to improve the function of incompetent valves by pericardial grafts and slings[3 14] have not yet proved wholly successful and until we have a reliable operation for mitral incompetence the condition of the mitral valve must be very carefully assessed before valvotomy is undertaken

In severe mitral stenosis the pulmonary vascular resistance is almost invariably increased and high *levels of pulmonary arterial pressure are commonly* recorded There is little doubt that both functional[15–18] and organic[19 20] narrowing of the smaller pulmonary arteries occurs and may be proportional to the degree of pulmonary hypertension[21] According to Lewis et al.,[22] when the area of the mitral valve (calculated by the formula of Gorlin and Gorlin[23]) is 1·0 sq cm or less and the pulmonary venous pressure rises to levels close to the colloid osmotic pressure of the plasma, narrowing of the smaller pulmonary arteries protects the pulmonary capillaries from the onslaught of the hypertrophied right ventricle By contrast, McGregor et al.[24] found that inhalation of oxygen produced a fall in pulmonary arterial pressure in 13 patients with increased pulmonary vascular resistance and they suggested that constriction of the pulmonary arterioles might be the result of anoxia secondary to pulmonary congestion and œdema rather than a protective change induced by pulmonary venous hypertension. The exact mechanism is still undecided, but pulmonary hypertension is an indication for operation,[1 2] and often a *fall* in pressure follows successful valvotomy[1 25] Low grade active rheumatic carditis, which may be very difficult to detect, may militate against success Valvotomy obviously cannot be considered in the presence of *acute carditis, but vague joint pains* and a moderately increased erythrocyte-sedimentation rate or anti streptolysin titre may have to be ignored when urgent symptoms of mitral stenosis demand operative relief. Even in cases where there is no clinical evidence of active carditis, biopsy material taken from the left auricular appendix at operation shows changes suggesting active carditis in 30–50% of cases[26] but these stigmata are not incompatible with excellent operative results[3 24] Auricular fibrillation, while not a contra-indication to operation indicates added risk, partly because of possible embolism from the left *auricle during operation and partly because the* disease is likely to be at a later stage than in cases where there is no fibrillation.[1] Fibrillation develops

after operation in some 30% of patients, and in half of these it becomes established despite attempts at conversion to sinus rhythm [1] Heavy calcification of the mitral valve is an unfavourable feature which may prevent adequate valvotomy [1]

The results of valvotomy are best in patients under the age of 40, with slight or moderate cardiac enlargement, pure tight mitral stenosis (usually with pulmonary hypertension), slight or absent valvular calcification, sinus rhythm, and no other valve lesion A large heart, auricular fibrillation, heavy valve calcification, or slight mitral incompetence do not contra indicate valvotomy but limit the improvement Severe aortic incompetence and predominant mitral incompetence are absolute contra-indications to mitral valvotomy Tricuspid lesions do not necessarily contra-indicate operation,[1] while the development of operations for the relief of aortic stenosis [27] may make simultaneous aortic and mitral valvotomy possible A history of systemic embolism is now usually regarded as an indication for operation rather than the reverse [3] Mitral valvotomy should be considered in any patient with progressive symptoms due to mitral stenosis, and is urgently indicated in the presence of attacks of paroxysmal dyspnœa at rest and pulmonary œdema, especially in pregnancy [1 2 28] Assessment of benefit from the operation at present depends mainly on improvement in, or disappearance of, symptoms, changes in the physical signs of mitral stenosis and pulmonary hypertension, diminution in heart size, and reversion of cardiographic signs of right ventricular hypertrophy Cardiac catheterisation may reveal a fall in pulmonary arterial pressure after operation, but postoperative catheterisation is not always practicable or desirable, and other objective tests of improvement, such as those of respiratory function [29] and exercise tolerance,[30] are required

Many questions have still to be answered Will the mitral valve become narrowed after valvotomy as a result of further attacks of rheumatic infection or fibrosis, how may low-grade active carditis be detected, how treated, and how prevented, what is the mechanism of dyspnœa and of the pulmonary vascular changes, and how can the degree of mitral incompetence be reliably detected before operation ?

Tuberculous Meningitis

FURTHER welcome evidence of the value of isoniazid in the treatment of tuberculous meningitis is described in our columns this week Dr FLETCHER estimated the isoniazid levels in the cerebrospinal fluid (C S F) in 15 patients with tuberculous meningitis by two chemical methods, and controlled the results by a biological method Despite the vagaries and difficulties of the chemical methods, he found that he was measuring active isoniazid With a daily dosage of 200 mg adequate bacteriostatic levels prevailed throughout the illness, thus confirming the biological findings of KLEE [31] and GEHRT [32] With a daily dosage of 10 mg per kg of body-weight (two or three times the former dosage) the C S F levels were significantly higher, but, while there was still no evidence of toxicity with these doses, FLETCHER suggests that little purpose is served by having very high le circulating isoniazid since these are not nec associated with higher therapeutic activity TORRES GOST reports on large series of p with tuberculous meningitis who received int cular streptomycin combined with oral and intr isoniazid He emphasises the great improvem the outlook since isoniazid was introduced his first 100 patients given a three month there were only 6 deaths Of the others, 6 under observation for 3–7 months after their ment, 34 of these had been discharged to their without relapse, while 27 were still in hospita 10 relapsing The relapses were mild and resp well to further treatment In 7 cases there mild paralytic sequelæ, but none involved disability TORRES-GOST remarks that supp of the acute phase does not necessarily impl manent cure, and it will be instructive to see follow-up of this series and compare it with the after streptomycin alone, as given by DEBRÉ [33] reported a survival-rate of just under 50%, most of the deaths in the first 6 months) an CAIRNS and SMITH [34] (survival-rate of 50–60% 18 months) It may seem, in view of FLE work, that intrathecal administration of iso may be unnecessary, but TORRES-GOST fou intolerance to the intrathecal injections, nor dif in giving them GEHRT [32] has shown, too, that thecal isoniazid does not cause an increase i C S F cell or protein content Dr ANDERSON a colleagues (p 691) obtained successful resul giving streptomycin intramuscularly and intrath for 1 or 4 weeks only and relying mainly on iso (10 mg per kg of body-weight daily for 16 w Although in 3 patients *out* of 7 the disease "advanced" on admission, they had no de (CLARK et al [35] reported 3 deaths among 10 pa with tuberculous meningitis treated with iso alone) ANDERSON et al chose comparable co from patients previously treated with streptom and showed that the temperature fell and the returned to normal more rapidly in the pa who were given isoniazid than in those treated streptomycin, in those given isoniazid the cl recovery was very rapid They point out tha patients were much happier with the smaller nu of intramuscular and intrathecal injections C et al [35] suggested that much of the intrathecal i ference could be avoided by giving isoniazid by and streptomycin by mouth and intramuscul These clinical results agree fully with the histolo findings of RITCHIE, TAYLOR, and DICK,[36] who n that the lesions of miliary tuberculosis and tuberc meningitis undergo resolution during treatment isoniazid, while with administration of streptom similar lesions become fibrosed, in patients tre with both agents, the isoniazid effect predominate

In deciding on the treatment of choice in tubercu meningitis, the possibility of giving only isoniazi mouth must be considered Its action is rapid effective, and its administration involves no unpleas

ss The Medical Research Council,[37] however showed at a third of all patients with pulmonary tuberculosis ated with isoniazid alone developed resistant tiants in 3 months, and this figure was reduced 2% when streptomycin and isoniazid were used in mbination Possibly these figures apply only to open' lesions, with the "closed' lesions of iliary *tuberculosis and tuberculous meningitis* the k of resistance might be much smaller Even so, would seem desirable to use a combination of both, the expense of some unpleasantness to the patient the form of intramuscular streptomycin especially this does not impair the efficacy of the isoniazid [38, 39] nce sufficient isoniazid enters the C.S F after al administration to be bacteriostatic, intrathecal jections, using the non irritant isoniazid, may per ps be confined to very acute cases when lumbar ncture is being done for diagnostic purposes It mains to be seen how little streptomycin is needed prevent the development of strains resistant to ther drug We need now to know the results in a ries of patients treated with isoniazid by mouth ily and with streptomycin by intramuscular injec on every second or third day Variants resistant to her streptomycin [38] or isoniazid [39] may be present fore any treatment is given, in which event the use *p* aminosalicylic acid with the other drug may have be considered In this form of tuberculosis the m must be to get the lesions to resolve as completely possible, but it is unlikely that any treatment ll prove universally successful

The Death Sentence

EVERY year some dozen people are judicially hanged England and Wales and their deaths are often tended by much unwholesome public excitement [40] it this important effect of executions since it nnot be abolished without abolishing the penalty elf did not fall within the terms of reference of the yal Commission on Capital Punishment [41] The mbers of the commission were called to discuss ly ' whether liability under the criminal law in eat Britain to suffer the death penalty should limited or modified and if so to what extent and what means', and they were expressly told the continuance or discontinuance of capital ishment was not for them to consider [42]

In this country liability to suffer the death penalty is already considerably modified by the Royal prerogative of mercy Of 1210 murderers sentenced to death in the first fifty years of our century, 23 had their conviction quashed on appeal 47 were certified insane and 506 were reprieved In every case the Home Secretary had the task of reviewing all the *circumstances extenuating the crime—including those* which had not been brought into evidence at the trial—and of deciding whether he could conscientiously ask the Sovereign to exercise the prerogative It is a curious system throwing much responsibility on the Minister and his advisers, and causing a solemn judgment to be pronounced unnecessarily upon a large number of frightened people yet as the report puts it the system ' works well in the sense that it produces results generally regarded as broadly satisfactory —' Broadly satisfactory ' that is, within the law as it stands at present Similarly in so far as it is possible to manage an execution by hanging humanely for the victim, the methods applied in our prisons are humane in England and Wales the time elapsing between the summoning of the prisoner and the act of execution is 9–25 seconds—one of the most impressive facts in the report But of course no expedition in the final act can relieve the prisoner and his family of the mental anguish of the weeks following the sentence, with its alternating periods of hope and despair

Hanging itself is believed to be an immediate and painless death comparing favourably in these respects with electrocution and lethal gassing Members of the commission visited America in order to establish this and the report gives their sound reasons for believing it to be so Nevertheless judicial hanging is claimed to have a ' uniquely deterrent ' effect which—if it exists—must be due to the grim associations of the gallows Actually there is no clear evidence that it has such an effect and there is no particular reason why it should Murderers do not form a homogeneous group many of them act under sudden provocation and murder is their solitary act of criminal behaviour others are not of a type to be deterred by anything demanding an act of imagination. The commission sum up by saying

> there is no clear evidence in any of the figures we have examined that the abolition of capital punishment has led to an increase in the homicide rate or that its reintroduction has led to a fall

The idea of the ' uniquely deterrent ' effect however influences public opinion, and so does the desire for retribution which is used by some as an argument against the introduction of euthanasia.

Why should a man who has coshed an old woman" the plain man understandably asks get an easier death than most of us can expect in the course of nature ?' The commission, however, state plainly their approval of the principle of euthanasia ' if we could have been satisfied that executions could be carried out in this way quickly, painlessly and decently in all cases we should have recommended its adoption unanimously ' They were deterred, curiously enough by the difficulties put before them by medical witnesses who seem to have been more anxious to ensure that no doctor should take part in an execution than to give the problem detached consideration The commission do recommend, how

Royal Commission on Capital Punishment, 1949–53 *London: H.M. Stationery Office 1953 Pp 506 12s 6d*

The members were Sir ERNEST GOWERS (chairman) Sir ALEXANDER MAXWELL, formerly permanent under secretary to the Home Office Earl PEEL, who resigned in 1950; Sir WILLIAM JONES, formerly clerk of the peace for Denbighshire; Dame FLORENCE HANCOCK chief woman research officer of the Transport and General Workers Union; Mrs. E. D C CAMERON (Miss Elizabeth Bowen the novelist); Mr JOHN MANN convener of the Lanarkshire County Council; Mr N R FOX, Q.C. recorder of Bournemouth Mr HORACE MACDONALD member of the executive committee of the Working Men's College; Prof G A MONTGOMERY Q.C., professor of Scots law at Edinburgh Mr LEON RADZINOWICZ, director of the department of criminal science at Cambridge; and Dr ELIOT SLATER, physician in psychological medicine at the National Hospital for Nervous Diseases ever, that this question should be periodically examined, with a view to a change of system being proposed to Parliament We are fully of their opinion, for whatever risks there may be in substituting euthanasia for judicial hanging, there can be no doubt that such a change would relieve beyond measure the sufferings of the condemned man's family, and do much to diminish the morbid interest of the public We also warmly support their recommendation (unfortunately not unanimous) that the death penalty should not apply to anyone under 21, the accepted age of adult responsibility

The outstanding defect of the law of murder is that it provides a single punishment for a crime varying widely in culpability fifty cases reviewed by the commission, in an appendix, show vividly how impossible it is to speak of "murderers as a class" We, as doctors, wish to feel confident that the death penalty does not befall any patient who, because of mental illness or abnormality, kills another person, and in recent years our concepts of mental illness and abnormality have so widened as to affect the legal definitions set out in the McNaughten rules The commission suggest that the rules might be extended to cover the fact that in some cases the accused, though he may know the nature of his act, and know that it is wrong, may be incapable of preventing himself from committing it They think it would be even better, however, to abrogate the McNaughten rules and leave the jury to determine whether at the time of the crime the accused was suffering from disease of the mind or mental deficiency to such a degree that he ought not to be held responsible This would take account of emotionally disturbed patients, including many guilty of sexual crimes, and of other abnormal people, including those of psychopathic personality, but of course it is difficult to know how the change would work out in practice—some juries perhaps being ready to accept psychological explanations while others were not It is disappointing, in this connection, that the commission specifically do *not* recommend a change of procedure which many of us have long thought desirable, and not only in murder cases—namely, the appointment of expert medical witnesses by the court rather than by the prosecution or the defence This, they say, would mean a fundamental change in the procedure of the courts and would have repercussions beyond the field of their inquiry

They do, however, propose that in England and Wales the mental state of every prisoner charged with murder should be examined by two doctors, of whom one at least should be a psychiatrist of standing who is not a member of the prison service, and the other usually an experienced member of that service The judge, in both England and Scotland, should be given the power, they think, to raise the issue of insanity, to call relevant evidence, and to put the issue to the jury, if he has reason to believe that the accused may have been insane at the time of the offence, and that the trial of this issue would be in the interests of justice, and they urge the immediate need for the establishment of an institution for the detention and treatment of psychopaths and other prisoners who are mentally abnormal though not insane, and for research into the problems of psychopathic [illegible]lity.

Much comment has already been excited by the commission's revolutionary suggestion that the j having in the first part of the trial decided the question of guilt, should then be presented w evidence of extenuating circumstances, and be as to say whether these were sufficient, in their opin to make a death sentence inappropriate The system, they say, is found to work well on the wh in countries where it has been adopted Whet such a system would be acceptable here is a mat for discussion with the legal profession, but it noteworthy that the commission believe that, it is not acceptable, this country has reached a st at which little more can be done effectively to the liability to suffer the death penalty The is would then become whether capital punishment sho be retained or abolished And, indeed, we belie this to be the live issue It seems that the mission have worked very hard and conscientio to find ways of reducing judicial executions in system where they are already as limited as exis law allows Their recommendations would red the numbers sentenced to death and then repri (which would be an unquestionable gain), and wo also reduce slightly the number at present exec —particularly among those who are mentally a but not insane, in so far as these can be detected present psychological methods The public consc might then revolt against sparing the untreat psychopath and executing the sane man, pos capable of reform But surely it is time to be d altogether with a penalty which can never do m than rough justice to any criminal, which al always entails suffering to innocent people, and wh helps to keep murder and murderers perpetually in limelight

Annotations

EPIDEMIC VOMITING

"EPIDEMIC vomiting" ("epidemic nausea," "w vomiting disease") is an entity on its own, and seve striking epidemics have been recorded in the past years, notably in girls' schools[1–3] Webster[4] has recorded another epidemic of some 313 cases in a g school This began at the end of September, sk rose to an explosive peak on Oct 11, and faded gradually over the next few days The illness confined to the school and family contacts, and these groups the attack-rate was high It appeared be spread by close personal contact, and to have incubation-period of less than 5 days The not symptoms were abrupt onset of vomiting, gener with profound prostration (75% of cases), na (28%), headache (40%), abdominal pain (5 giddiness (36%), and diarrhœa, slight and transi with only one or two loose stools (30%) People of ages were attacked and the clinical features w constant throughout the whole age range The dura of symptoms varied from a few hours up to a day or recovery was rapid, and there were no sequelæ In outbreak there seemed to be no associated upper res tory infection There was nothing to suggest infe from the school water-supply or even from the s canteen, and, as in other outbreaks, the infection thought to be airborne Such virus studies as were d on blood and nasal washings yielded negative results

Out of the welter of ill-defined acute virus infections which seem to exist in this and other countries, this mild winter epidemic infection seems to be qualifying for general recognition.

'URÆMIC LUNG—FLUID LUNG?"

In an article under this heading Alwall et al[1] answer their own question by saying that this is the first of a series on 'electrolyte-fluid retention Neither of the two names is particularly pleasing since the disturbance that they describe has often been observed in patients without uræmia, while a fluid lung' is literally impossible But the fact that exception can be taken to both these terms does not mean that a more suitable name is easily devised. Pathologists agree that the type of œdema found in the lungs is non specific and the syndrome could be defined as acute localised pulmonary œdema with X ray shadowing in association with acute fluid retention and left ventricular failure —a description that can hardly be shortened except by omitting one or other feature which differentiates this from other syndromes more or less closely related to it.

This type of acute localised pulmonary œdema was first reported in the 30s by Continental workers[2,3], who found it in association with renal failure and hypertension and ve it the name ' uræmic œdema. This name it has w retained with dwindling justification for twenty ars In 1941 the typical radiographic appearance was scribed of fan-shaped opacities radiating from the lum, but tending to spare the peripheral lung fields.[4] oniach,[5] who examined the lungs in four cases, found non infective albuminous and fibrinous pulmonary dema in various stages of organisation He pointed it[6] that the same type of œdema could occur apart om uræmia—for example, with cardiac failure due to yocardial infarction or mitral stenosis Pathologically e changes could not be distinguished from those of -called rheumatic pneumonia' He added that the peculiar butterfly shaped distribution of the transudate the lungs remains an enigma. Bass and Singer[7] ere perhaps the first to emphasise the importance of ft ventricular failure, noting the disappearance of the tered lung shadows as this responded to treatment they so cited Dock s explanation of the distribution of œdema ased on the relative immobility of the hilar parts of e lung by comparison with the periphery in which entilation might hinder the accumulation of fluid.

Alwall and his colleagues now bring forward clinical nd experimental evidence confirming the importance of uid retention in causing this type of pulmonary œdema hey studied fourteen patients with chronic renal failure nd two with anuria from acute tubular necrosis, all of hom were notably dyspnœic and had the characteristic adiographic appearances. Diarrhœa was induced by a aily dose of 200–400 ml. of 25% or 50% sodium sulphate o other fluid being given if the patient vomited, 100 ml f 25% sodium sulphate was given as an enema three or our times daily On this stern régime the patients eight fell by as much as 4 kg a day there was a ramatic recession of the pulmonary shadowing and yspnœa was relieved In experiments on rabbits the reters were ligated, a control radiograph was taken and n amount of "liquid corresponding to 15% of the ody weight was infused radiographic examination then howed extensive pulmonary shadowing which dis ppeared when the excess of body fluid was removed by ialysis In an addendum to their paper they mention he removal of a life menacing pulmonary œdema by five hours treatment with Alwall s type of artificial kidney[8]

Although retention of fluid may clearly precipitate acute localised pulmonary œdema many patients with massive œdema, as in type-II nephritis, have no dyspnœa and no pulmonary shadowing—suggesting that some additional factor promotes localisation of part of the excess fluid in the lungs The frequency of this type of pulmonary change not only in chronic nephritis, in which it was first described, but also in anuria and acute nephritis, suggests that this additional factor may be left ventricular failure secondary to hypertension The importance of cardiac failure has recently been emphasised both in anuria[9] and in acute nephritis[10] The recognition of acute localised pulmonary œdema is perhaps more important in these acute and reversible conditions than in chronic renal failure and the possibility of it strengthens the case for fluid restriction and complete bed rest in the management of anuria and acute nephritis

MENTAL NURSING IN DECLINE

Of the hospital beds in this country no less than 40% are in mental hospitals but this large group does not command anything like its proper proportion of our nursing resources. As is now widely recognised, the nursing service of mental hospitals though it includes many first-class men and women, is, in general insufficient and therefore poor Since trained staff are few, and recruits for training are getting fewer much of the burden of mental nursing is carried by people for whom no systematic course of training is at present laid down[11] This is a dangerous situation we could easily slip back to the cruelty and degradation of the old bedlams from which we are little more than a century removed.

A contributor to the *Male Nurses Journal*[12] makes some constructive suggestions He points out that many of the old chronic patients in mental hospitals do not need any mental nursing at all—only kindly care and general nursing of the type given in the geriatric wards of a general hospital or in rest homes for the aged. Such patients might well be transferred to such wards and homes, thus releasing beds for acutely ill mental patients likely to benefit by modern treatment Accommodation of the type suggested, however is still very scarce it would have to be greatly extended before this proposal could be put into practice Nevertheless, it would certainly promote economy in the use of qualified mental nurses and help to ensure that they were doing the work for which they were trained

Like us, this writer believes that student nurses in general training might well spend three months in mental hospitals This plan, we have suggested, might be tried first at Hill End, St Albans, where a teaching general hospital (St. Bartholomew's) and a mental hospital are already sharing the same buildings[13] He also proposes an interchange of administrators between general and mental hospitals, so that they may get a better grasp of each other s background and problems, and thus come to coöperate more easily In the manner of the *Prime Minister* in the days when he offered us blood and tears he calls for posters pointing out that nurses are needed in mental hospitals and that it is hard work demanding courage and patience. As a long term policy he advocates converting the mental hospitals into hospitals for the treatment of organic and functional nervous disorders (which would naturally include mental disorders) Such a hospital would carry neurological wards as well as wards for the neurotic and psychotic and would have an associated research unit The name of the hospital could then be changed to Somebody s Hospital for

Nervous Disorders", and thus, as he says, would soon be contracted to "Somebody's Hospital," and the term "mental nurse" to plain "nurse"—the most sensible name

Meanwhile recruitment to the mental nursing service could be fostered, he thinks, if the trained staff and the public were in closer touch The hospitals could hold open days, with full civic and press support, when visitors would be taken round the wards and laboratories on conducted tours Trained staff could give talks to women's institutes, senior schools, associations of teachers, and industrial and youth organisations Patients who are well enough could attend local meetings in which they are interested—of church groups, Women's Voluntary Service, farmers' unions, and clubs, as well as educational and Red Cross courses The leagues of Friends of Mental Hospitals should be helped to extend their activities to all parts of the country, where they are active they are already doing much to create good feeling between the hospitals and the public Such increased commerce between the hospital and the outside world would help to break down the isolation in which the mental hospital residents—patients and staff alike—at present live The hospitals are isolated in another sense each of them is a separate community, with its own customs and methods, and there is very little interchange of ideas—anyhow of nursing ideas—between one hospital and another It is a long-standing weakness of the service, which might be overcome more easily if there was some coordinating body—some association or group to which all mental hospitals belonged—which would publish information about the work of its various members

TINEA CAPITIS

THOSE dismayed by the advancing tide of warts may feel that the employment of a squad of reliable wart-charmers would be a legitimate charge on public funds The activities of the Ulster ringworm charmers [1] are less admirable Their good reputation, like that of some more orthodox practitioners, rests on the tendency of some diseases to get better without treatment This happens particularly often in human infections with ringworm fungi normally parasitic on animals

In dealing with a large epidemic of ringworm in Northern Ireland, Beare and Cheeseman [1] found it unnecessary to treat cases of tinea capitis due to *Microsporum canis* by the conventional method of X-ray epilation this they reserved for cases due to *M audouini* and *Trichophyton sulphureum* *M canis* infects kittens, which are the main reservoir of contagion Beare and Cheeseman's maps showing the distribution of their cases in Belfast indicate clearly that infections with *M canis* were sporadic, whereas those due to *M audouini* were concentrated in two main areas, suggesting case to case spread This is the usual experience, although according to Kligman [2] *M canis* can cause wider outbreaks when it mimics *M audouini* by producing non-inflammatory lesions with less tendency to rapid spontaneous healing

Thomas [3] has also reported that it is not essential either to treat *M canis* infection with X rays nor to keep infected children from school Whittle [4] has witnessed an epidemic of scalp infection with *M audouini* in which most cases responded to simple local measures It is true that he was dealing with a rather feeble variant of the parasite, but it is valuable to know that such variations in virulence occur Kligman's work, the most interesting on the pathogenesis of tinea capitis since the days of Sabouraud and Adamson, shows how far the course of infection may depart from what is usually expected

The main object in insisting on treatment is to protect not so much the patient as the community Beare and Cheeseman's report illustrates how careful clinical examination, good contact tracing, mycological investigation, and prompt treatment can curtail epidemics X-ray epilation is not the ideal routine treatment, for it requires faultlessly calibrated machines and skilled operators experienced in the technique, if disproportionate risks are not to be taken Dermatologists look forward to the development of antibiotics effective against fungi Those causing the various forms of ringworm live exclusively in keratin, and a substance may be found which, excreted by the horny layer, nails and hair, will offer the parasites their hemlock disguised as a favourite metabolite

GREAT EXPLORATIONS

Sir Henry Dale's friends have fortunately been able to persuade him to make, and to issue in one volume,[1] his own choice of his published writings He has written a charming and illuminating introduction, and has added retrospective commentaries to the individual papers These papers are landmarks in an eventful career some are also landmarks in the history of science In 1910 Barger and Dale introduced the word "sympathomimetic" to describe the action of various amines which parallel, in varying degree, the excitatory and inhibitory effects of sympathetic-nerve stimulation In 1914 Dale first described the pharmacology of acetylcholine, which his colleague Ewins had isolated from ergot, and drew attention to its muscarine like and nicotine like aspects In 1929 Dale and Dudley, searching for histamine in the spleens of ox and horse, detected enormous choline-like activity and announced the first chemical isolation of acetylcholine from animal tissue In 1933 Dale proposed the terms "adrenergic" and "cholinergic" There followed the well known papers, with Brown, Feldberg, Gaddum, and Vogt, on cholinergic transmission, the subject with which Dale's name is linked by every student of physiology in the world today

For the experimental pathologist another set of landmarks stands out In 1910 Dale and Laidlaw first described the pharmacology of histamine, noted the different distribution of its stimulating effect on plain muscle in a variety of species, and cautiously compared these actions with the phenomena of anaphylaxis In 1913 Dale found that plain muscle from a sensitised guineapig would contract if treated in vitro with a minute dose of antigen In 1922, Dale and Kellaway proved that such plain muscle would not contract to added antigen if free antibody were present in the bath And in 1927 Best, Dale, Dudley, and Thorpe isolated histamine chemically from liver and lung

Medical men will be glad to have these thirty papers bound together for convenient reference, but it is to the beginner in research that the book should make its most special appeal, for the introduction and comments and, not less, the selection and juxtaposition of the papers give unique insight into the scientist's work, into the growth of his ideas and of his skills Sir Henry tells some fascinating stories of lucky accidents with ergot and liver extracts and with sensitised guineapigs thought by others to be good enough for pharmacological experiments, but his assessment of the large part played by such accidents in his success will not be taken very seriously Many will suspect that they themselves have had similar opportunities and not known it The comments are models of modesty He blames himself for not having tested noradrenaline in 1910, when it was commercially available as 'Arterrenol' Of discovery in 1920 that adrenalectomy increases enormously the susceptibility to histamine shock he writes today ' My purely speculative suggestion of an unknown function of the suprarenal cortex might be made to assume a certain air of prediction if viewed in the light of what is now known but the fact that I made no attempt to follow that line of thought by further experiments, is sufficient evidence that I myself attached no serious importance to it at that time ' Exemplary caution in the use of drugs as physiological tools is shown in the paper with Laidlaw in 1912, in which it was proved that dilatation of the pupil by nicotine is not due as might have been thought, to direct action of nicotine on the pupil, but is due to stimulation of the adrenal medulla But perhaps the most important lesson here illustrated is that taught by Ramon y Cajal the need to ponder for years on particular subject-matter to achieve a degree of cerebral polarisation ' if important progress is to be made Thus, over years, the idea of chemical transmission took hold first for the autonomic, then for the somatic nervous system The conception of a rapid localised liberation and removal of acetylcholine has provoked, and been abundantly confirmed by, newer electrophysiological experiments which have accurately defined the conditions of synaptic and neuromuscular transmission

LABORATORY DIAGNOSIS OF SMALLPOX

THE cost of this country s freedom from smallpox —constant vigilance—is buried in the expense of the preventive services generally When the disease is detected at the ports and still more when it slips through the cordon energy is diverted to its control and the cost soars. An expensive administration comes into action The cost of vaccination, surveillance and hospital care can be readily measured but the toll on the national energy exacted by public apprehension cannot be estimated Confronted with a doubtful case of smallpox the medical administrator must choose between the risky policy of waiting and the expensive policy of action *The emergence of reliable laboratory tests has reduced materially the period of doubt* instead of depending on protracted clinical observation in a smallpox hospital, he can do tests which rapidly and convincingly aid the diagnosis often without moving the patient

The Ministry of Health has issued a brochure [1] on the laboratory diagnosis of smallpox for the information of medical officers of health medical officers of seaports and airports, and others who may be concerned in the diagnosis of the disease. The document includes notes on the tests available a reproduction of an article by MacCallum,[2] instructions for collecting and dispatching specimens, a list of laboratories available for performing the tests, and a list of the Ministry's clinical consultants in smallpox The limitations of the laboratory methods are noted, and emphasis is placed on the tests as aids to clinical diagnosis, not as substitutes for it.

The most useful tests are those in which the virus or its antigen is sought in the local lesions Direct microscopic examination of smears from early lesions rapidly confirms a clinical diagnosis but a negative result does not exclude the disease and the test is not reliable from the pustular stage onwards The complement fixation test is much more reliable and provides a result in twenty four hours. The suspected material (papule scraping vesicle fluid, or crusts) is used as antigen against a known rabbit-serum The third test is egg culture of the suspected material; the result is known in 48–72 hours. Occasionally egg-culture from the blood of febrile contacts in whom the disease is developing may give a diagnostic growth by the time the rash appears Tests for antibodies are less helpful because antibodies do not appear until the seventh day and recent vaccination interferes with the tests

With these aids the clinician is more favourably placed than he has ever been before In future every case in which a reasonable suspicion of smallpox arises will, no doubt be subjected to such tests Mistakes will still be made but they are likely to be less common and much less disturbing to the public

BACTERIAL L FORMS

THE obscurity surrounding the L forms of bacteria is due partly to technical difficulties and partly to the semantic problems which bedevil discussion of their origin fate and significance Pulvertaft [1] has made a commendable attempt to clear up some of the difficulties by proposing that The name L form should be used to describe the large plastic masses How far this restriction usage will find favour it is difficult to say From Klieneberger s first report in 1935 [2] onwards the definition has been very vague

Thus Klieneberger wrote Organisms L_1 and L_2 the structure and life cycle resemble closely the morphological development of pleuropneumonia Dienes [3] wrote of L type variants in cultures of various bacteria and of tiny secondary colonies similar in appearance and morphology to the L_1 variant of *Streptobacillus moniliformis* Dienes and Weinberger [4] stated: The peculiar forms which are the subject of this review are called L forms and their colonies and cultures are referred to as L type They continue:

In the description of the morphology of L type cultures the terms Small forms Swollen forms, and Large bodies are employed The latter two terms will be applied also to pleomorphic forms of bacteria Later in the same article they wrote the L forms grow from the large bodies as strands of refractile granules, and the large bodies either return to bacteria or grow into L forms

This appears to equate the L bodies with the small forms On the other hand Klieneberger Nobel in 1949 [5] said that the size and shape of the L bodies largely depended on the number and arrangement of the primary cell units, ' and referred to a large disc like body which because of its shape, size and structure must be regarded as an L body In a later paper photomicrographs of L bodies give the impression that these are small, pleomorphic masses.[6]

More recent accounts have done little to clear up the difficulties of interpretation The reports by Wittler [7,8] on the L form of *Hæmophilus pertussis* seem to refer to pleomorphic masses equal to or larger than the bacterial forms. Pulvertaft s report on the effect of antibiotics on growing cultures of *Bacterium coli* [9] contains a very good account of usage of the term L forms and appears to distinguish filamentous forms from L forms The usage in Stempen and Hutchinson s [10] account of large bodies in *Proteus vulgaris* is that adopted by Pulvertaft in his latest paper [1] but Dienes and Zamecnik [11] last year differentiated large bodies from L forms. Lately Howard Hughes [12] discussing L variants of *Bact. coli* has introduced yet another conception The essential feature of an L variant would be that growth continued while division was inhibited

Various workers claim to have found L forms in urine and Wittler [8] showed that *H pertussis* was in the L form when infecting mice. There is good evidence that L forms are more resistant to penicillin and other injurious

substances than the normal vegetative forms[7] An examination of the forms in which penicillin resistant organisms appear in vivo would be of interest, as also would be an examination of cultures that are being rendered penicillin-resistant in vitro Meanwhile we still need agreed definitions of the terms L forms, L bodies, L type cultures, small forms, and swollen forms

CHEST WOUNDS IN WAR

CHEST wounds have always been one of the most lethal injuries in warfare Sauerbruch, examining in 1914 the cause of death in 300 soldiers, found that 37% of them had died of gunshot wounds in the chest It is estimated that during the hostilities in Korea one-third to a half of all the men killed died as a result of wounds in the thorax, and that in the exposed forward area thoracic injuries are twice as common as abdominal Nevertheless, for the injured man who survives the original shock and damage, the chances of recovery have dramatically improved It is estimated that in the first world war 27% of soldiers with chest wounds died, but in the second world war only 8% The circumstances of the different fields of war have to be taken into account, but the improvement is undoubtedly due largely to improved methods of treatment

King and Harris[16] have now described their experiences with 405 major thoracic casualties in Korea As soon as an injured man is brought under medical care a decision has to be made as to whether he requires emergency treatment or can be treated more satisfactorily after evacuation to the base Emergency treatment is needed for such complications as continued bleeding, abdominothoracic injuries, and pressure effects which require relief For these, immediate operation is imperative, and in this Korean series, which concerns mainly the U S Navy and Marines, 52 thoracotomies and 43 laparotomies were done in the forward area The majority of the wounded were, however, the victims of hæmothorax, which was most satisfactorily treated on return to base, and the average time between the injury and the definitive treatment in this series was 7 days Hæmothorax is the principal factor in chest wounds Treatment should consist in early and complete aspiration, with the knowledge that this can be undertaken without any fear of starting further hæmorrhage King and Harris, who emphasise the importance of this early and complete aspiration, found that on an average they aspirated each of their patients three times, withdrawing almost a litre of fluid blood each time, but one patient was needled sixty times before the fluid was completely removed and the pleural space obliterated by re expansion of the lung An earlier belief, that aspiration could be accompanied by air replacement, should be discarded, because this measure does not encourage the lung to re-expand, and as a result a dead space is formed which may be the site of secondary clotting and infection If all aspirations are kept closed, and the fluid is withdrawn without any air being admitted, the lung will inevitably re expand and reach its proper position against the chest wall

King and Harris feel that the operation of decortication or pleurectomy, which found favour towards the end of the late war, is unnecessary if efficient closed aspiration is carried out, and they did this operation only 4 times Their use of $^1/_2$% acetic acid and 15% glycerin in normal saline as an irrigating agent was felt to be of value in facilitating aspiration and preventing infection, which is likely to arise in a long-standing hæmothorax There were only 25 examples of infection—owing, partly, to the continuous use of antibiotics 80% of their patients recovered completely and were fit for duty in 90 days The success of these methods may be judged by the fact that the mortality was only 1% Such results are obtained only with great patience and care

"FABER"

ANYONE who has tried to define a term, describe a method, or summarise a hypothesis has reason to understand the difficulty of compiling a dictionary containing thousands upon thousands of definitions, descriptions and summaries But, though they can never be perfect dictionaries are essential tools of learning, and in medicine as elsewhere it is very necessary that we should possess such tools, well constructed and kept sharp by frequent revision The *Faber Medical Dictionary*,[1] which made its first appearance last week, should be useful not only to doctors, dentists, and nurses but also to the many other people working in the National Health Service and elsewhere who are continually confronted with medical terms The profession throughout the English-speaking world has been well served by American dictionaries of high merit, but to those of us who read and write in this country it is no small satisfaction to possess at last a work of comparable scope which is British in its spelling and usage

Sir Cecil Wakeley, F R C S, the editor, and his associates, give us a large but easily handled volume of the kind that lures the reader away from his proper business Aiming at comprehensiveness, Sir Cecil has provided much that is unfamiliar and entertaining, and of course he is justified in so far as one of the functions of a dictionary is to explain words that ordinary people do not know by sight On the other hand he has put in a great many terms which, if they have ever really been alive few of us would wish to see brought back from the dead and if these were excluded from the next edition there would be room for more of the up to date information which is a feature of the work If, as at present, an attempt is made to include the better known proprietary names of drugs, the selection might well be larger, and though there is much to be said for making each item sufficient unto itself, there should always be cross references between proprietary and official names (For example Pentothal should be linked to Thiopentone) Further it would surely be convenient if this British dictionary made use invariably of the names approved by the British Pharmacopœia Commission (There are entries under Desoxycorticosterone, and Deoxycorticosterone and DOCA, but not under Deoxycortone, the *B.P* term An impression given by casual perusal is that the advancing science of endocrinology does not in fact get as much attention as do monsters in their infinite variety thus Cortisone is rather curtly dismissed as "one of the hormones of the adrenal gland used in the treatment of rheumatoid arthritis," and there is no mention of compound F On the long and entertaining controversy over "trophic" and "-tropic" hormones, "Faber" speaks with a certain ambiguity we find both Adrenocorticotrophic and Adrenocorticotropic (though the derivation here does not mention *trephein*), but neither of the adjectives Thyrotrophic and Thyrotropic gets an entry, though the latter is used in describing thyroxine We must take note, however, that another long contest has ended by Radiograph finally knocking out Radiogram Though the better man, the latter made the mistake of fulfilling engagements elsewhere

Taking the offensive, perhaps, against potential critics Sir Cecil and his colleagues describe Pessimism as "a neurotic disposition always to see and to expect the worst" This downright definition, though it omits philosophical conceptions, fulfils at least the editor's aim to be concise and readily intelligible It illustrates the robust good sense which initiated and infuses his book and which will win it many friends

International Conferences

MICROBIOLOGY

FROM A VIROLOGIST

At the 6th International Congress of Microbiology held in Rome during the week of Sept 6 2000 delegates gathered from all over the world to meet their colleagues from foreign countries, discuss their scientific problems and listen to some 1200 scientific communications Faced with such formidable numbers of delegates and communications, many organisations would have wilted The Italian organising committee, under its secretary general E Biocca might have been forgiven had they decided to hold the meetings at the Colosseum and throw the speakers into the arena instead they made a magnificent job of steering a large congress through a most complicated scientific and social programme

When the delegates registered for the proceedings they received among handsome gifts, three volumes of summaries of the communications weighing 6½ lb, and a guide-book and leaflets to help them to find their way through this maze of scientific knowledge At past microbiological congresses it has been possible for delegates, if they wished, to keep an eye on the main events taking place in perhaps five or six sections running simultaneously But the 6th congress found it necessary to divide itself up into 22 sections, and in addition a number of symposia were run at the same time As a result, even the most enthusiastic delegate had great difficulty in finding out what was happening even in his own small specialty Truly Dame Microbiology has developed a middle-aged spread—probably the result of ingesting too many scientific papers. There is a great need to remove some of her unsightly bulges before the next congress, but ways of doing so are by no means easy to prescribe Perhaps one method would be to have all communications published in the proceedings but to limit the number of communications to be read at the congress. Each country might be allotted a quota of communications to be read, and national committees would then select the required number from the communications submitted Such a plan has many disadvantages yet some such arrangement is urgently required if future congresses are not to develop into Microbiological Towers of Babel. A scheme of this type might also help to remove anomalies such as the reading of seven successive papers by one delegate.

Many must have been disappointed that only a small number of microbiologists from the U.S.A were able to attend. On the other hand it was good to see delegates from Russia, Poland, Czechoslovakia, and Hungary once more.

Work on Viruses

Faced with such a large variety of subjects there was nothing to be done except to show the most resolute single-mindedness by choosing one section and attending it regularly, the discriminating chose the section on animal viruses

T Wesslen (Stockholm) described a method of growing vaccinia virus in tissue culture of bovine embryonic tissue Embryos are easily obtained from the slaughter house and Wesslen's technique seems to offer a simple and cheap method of producing bacteriologically sterile vaccine It will be interesting to see the results of human vaccination tests with the tissue-culture virus.

A. W Downie and D R W Haddock (Liverpool) reported a variant of cowpox virus which differed from the parent virus in cultural characteristics and showed reduced animal pathogenicity It was interesting to find that from apparently pure cultures of the parent virus variants occurred with an average frequency of about 1 in 130 This surprisingly high figure might have made bacterial geneticists pause and wonder

A Macdonald and K. McCarthy (Liverpool) discussed natural heat labile inhibitors of a number of viruses present in normal animal and human serum and suggested that they might play a part in protecting against infection with small doses of virus

J B Brooksby (Pirbright, England) showed how the tissue-culture technique of Fulton and Armitage could be applied to the titration of foot-and mouth-disease virus—a method which should prove of great value in the study of this most difficult disease.

R Lundström (Stockholm) estimated the risk of immaturity congenital abnormalities and stillbirth as three times greater in the children of mothers who had contracted rubella during the first to fourth months of pregnancy than in those of controls Contacts of cases of rubella who were previously immune also showed an increased proportion of congenital abnormalities in their children C H Andrewes F.R.S found this difficult to reconcile with the protective action of gamma globulin against rubella and it seemed possible that the small numbers of cases might have created this impression

M M Sigel, A. J Girard and E G Allen (Philadelphia) studied the mode of multiplication of meningopneumonitis virus and found that the latent period of virus growth could be greatly prolonged by treating the tissues with aureomycin

C H Andrewes D Chapronière, A Gompels, H G Pereira and A T Roden (Salisbury England) announced to a most attentive audience their finding that the common-cold virus had been cultivated in tissue cultures of human embryo lung [1]

H B Donald Alick Isaacs and Forrest Fulton (London) confounded the mathematicians and philosophers with their conclusion that at least ten influenza virus particles were required to constitute one infective dose and Fulton and Isaacs showed that when incomplete virus was grown on the chick chorion it showed unexpected signs of life H P Chu (Cambridge) reported that the viruses of the influenza group agglutinated spermatozoa

H L Wolff (Leyden) observed that adults who had previously had mumps in childhood react on contact with the virus by producing a rapid increase in complement-fixing antibody He used this in order to make an early serological diagnosis of mumps By examining the patient's serum and that of his parents, nurses &c Wolff is often able to reach an accurate diagnosis of mumps on the first day of illness.

I Archetti (Rome) compared neutralisation and agglutination inhibition tests in the study of influenza vaccines and found the former a more sensitive method.

POLIOMYELITIS

The recent technical advances in the study of poliomyelitis were reflected in many interesting communications and discussions on this subject. J D Verlinde (Leyden) described the distribution of the three types of poliomyelitis virus in Holland; and he stimulated discussion of this subject by speakers from France Sweden South Africa, and the U.S.A Although the types were differently distributed in these countries there seemed to be general agreement that type 1 virus was the commonest and that type 2 virus tended to be associated with sporadic cases.

A B Sabin J Winsser, and W A Hennessen (Cincinnati) had some extremely interesting findings on what they called the pathogenic spectrum of poliomyelitis viruses in different tissues Poliomyelitis virus strains after continual cultivation in one tissue showed increased pathogenicity for that tissue but greatly reduced pathogenicity for tissues to which they had earlier been adapted Clearly this is a field of great importance for those seeking stable avirulent variants of poliomyelitis viruses for use in vaccines, and the phenomenon will repay careful investigation with all the virological, genetic, and serological techniques available

---

G BARSKI, V MONACI, and M ENDO (Paris) have recently reported that that most dispensable of human organs, the tonsil, provides a convenient source of fibroblasts for cultivating poliomyelitis virus in vitro, and these cells have been most useful for a study of the detailed histopathology of the virus lesion

TH FRANCIS, jun, and L W CHU (Ann Arbor, Michigan) found that poliomyelitis virus was adsorbed to tissue constituents of the grey matter of the brain of monkey and man Other tissues of these animals or the same tissues from other animals did not absorb the virus This "receptor like" substance appears to be protein in nature and may prove a valuable object in the study of poliomyelitis-virus growth

A J RHODES (Toronto) described the use of synthetic nutrient media in tissue cultures infected with poliomyelitis virus Those who discussed his paper seemed curiously unimpressed with the advantages of having a medium of known chemical composition, but Rhodes produced sound theoretical reasons for his choice

J L MELNICK, J T. RIORDAN, E C CURNEN, and A D MACRAE (New Haven, Connecticut) found a number of unidentified pathogenic agents during their attempts to isolate poliomyelitis virus in tissue culture, some of these may be new viruses, but there is always the possibility that an unidentified agent may be a weakly pathogenic variety of a known agent or a mixture of two known viruses

A SVEDMYR and L KJELLEN (Stockholm) discussed their experiences with the complement fixation reaction in poliomyelitis using antigens prepared from tissue culture virus by improved techniques

D HORSTMANN and R W, MCCOLLUM (New Haven, Connecticut) demonstrated the occurrence of viræmia during poliomyelitis and pointed out that the beneficial action of gamma globulin in poliomyelitis is not necessarily due to its stopping the viræmia

S GARD (Stockholm) found that during the late stage of an epidemic of poliomyelitis quite a high proportion of infants and young children, but not adults, excreted virus He assumed that the positive individuals represent a selection of persons not previously exposed to virus and suggested that the percentage of positives among the non immunes rather than of the whole population should be taken as significant of the rate of dissemination of virus in the community This, incidentally, may be one of the last epidemics in which isolation of poliomyelitis virus was made by inoculating monkeys

OTHER VIRUSES

J S F NIVEN, A W GLEDHILL, and G W A DICK (London) showed the dual character of the ætiology of mouse hepatitis *Eperythrozoön coccoides*, an organism with an unexpected ability to penetrate bacterial filters, was found to enhance greatly the pathogenic action of the mouse hepatitis virus and of a number of biologically related agents

R M TAYLOR (Cairo) described the isolation of a number of viruses from human blood and mosquitoes in Egypt He identified Coxsackie and West Nile encephalitis viruses and possible new agents

There were some rather sensational discoveries reported under the heading "diseases of possible virus ætiology," but it seems likely that the ætiology of many of these conditions will remain in doubt for some time

Symposia

In parallel with the congress, a number of symposia were organised by the Instituto Superiore di Sanita In perhaps the most stimulating paper R DULBECCO and M VOGT (Pasadena, California) described the techniques for studying the growth of animal viruses Previously workers with bacteriophages have enjoyed the advantages of being able to count the concentration of infective bacteriophage in a preparation by spreading it on a single suitably inoculated petri dish, and to measure by appropriate methods the yield of bacteriophage from a single cell Now Dulbecco has adapted these techniques to the study of animal viruses grown in tissue culture Animal viruses such as those of equine encephalomyelitis and poliomyelitis were found to produce plaques analogous to bacteriophage plaques when spread on the surface of a thin layer of tissue-culture cells grown on glass From such plaques it is possible to isolate pure "colonies" of virus and to envisage the carrying out of accurate genetic studies Dulbecco also carried out kinetic studies of the growth of virus in suspensions of separate cells and in single cells, and he found that the release of virus from these cells was gradual over a long period of time, unlike the sudden release of bacteriophage from bacteria on lysis. Both from the point of view of what was already accompl and from its future possibilities this was one of the most important contributions to the congress

R W SCHLESINGER (New York) gave a most stim account of the multiplication of influenza virus He was anxious to find some rational explanation for the enzyme action of influenza virus and saw in it some f nda activity connected with multiplication rather than accidental property of little practical value to the virus He presented interesting results to show the variation in concentration of the enzyme substrate during the course of infection, and concluded, as Dulbecco had de that the cells produced virus over quite a long period of time

P VON MAGNUS (Copenhagen) described his work with incomplete influenza virus, made in an attempt answer the puzzling question whether incomplete virus is an immature developmental form or mature but defective virus His exhaustive experiments cover almost every aspect of the phenomenon, and he presented reasoned accounts of the factors governing the appearance of incomplete virus He emphasised the heterogeneity among incomplete virus particles, and GARD, as result of his analyses of the lipid content of the virus forms, supported this strongly

Apart from the communications there were numerous formal and informal scientific meetings associated with the congress Thus the International Committee on Bacteriological Nomenclature decided that henceforth *Bacterium coli* should become *Escherichia coli* The subcommittee on virus nomenclature were less fortunate they agreed that Professor Gard should take the minutes and this represented the major area of their agreement Nevertheless the congress produced a great deal informal agreements, friendships made and renewed and collaborations established Italy was in many ways an ideal country for the congress, and the friendliness and sunny temperament of the Italian and his climate soon communicated themselves to the delegates

Perhaps the Italian motorist's method of indicating the direction he wished to go by driving straight at may have stimulated morbid reflections on the half of the Italian pedestrian, the leisurely progress of Italian waiters may have set in motion a few doubts as to the true meaning of the word *subito* Perhaps, too, scientists may have felt a little sad when they heard about difficulties which a young Italian may have to overcome if he wishes to pursue a research career, scientists this country are not accustomed today to hearing that young university workers may have to buy their own animals and apparatus if they wish to do research however they may have reacted to this or that a of Italian life, there were few delegates who left Rome without a deep impression of the beauty and majesty of a great city and a great civilisation

PHYSIOLOGY

FROM A CORRESPONDENT

MOST people associate Montreal with McGill and McGill with Osler But Penfield, Collip Meakins, Babkin and Browne have also made Montreal a world medical centre, and Masson and Selye have attracted budding histologists and experimental endocrinologists from all over the world to the young Université de Montréal which has become the French Canadian Sorbonne

The 19th International Physiological Congress, held in Montreal between Aug 31 and Sept 4, went off with élan. The atmosphere of the city is unique Although 65% of its population is of French Canadian descent its strategic position as the gateway to Canada filters out many Europeans who come to settle in the country In winter and in summer it is also a playground and business centre for Americans from New England and the East Coastal States Its flavour is a mixture of French Canadian glamour shrewdness and finesse of English Canada's adventurous foresight; and of American hustle and know how These attributes and the peculiar saltiness common to all great ports, have made it the cosmopolitan centre of North America—and a gay one at that.

Some 3000 members and associate members from 48 countries, including a large contingent from the United Kingdom, registered for the congress, which was notable for the tremendous amount of work presented and for the overwhelming hospitality of the Canadians.

Dr CHARLES BEST co-discoverer of insulin, in a presidential address opened the congress and also gave a display of verbal virtuosity in welcoming the members in six languages, including Gælic and Mohawk

During the week seven symposia were given in the Salle des Promotions of the Université de Montréal while over 700 individual papers and 60 demonstrations were given at McGill. Buses shuttled between the granite grey ivy walled, tree-shaded McGill campus and the barren yellowness of Montreal's modern university McGill has the classic veneer of any Scots university and flows down the commanding slope of Mount Royal into the centre of the city The Université de Montréal is built high on Mount Royal on the north western slope of the mountain overlooking the suburbs Its main building, a phallic tower rears a corona high above the factory modern classrooms and laboratory buildings which cluster around it

When one got tired of symposia and papers or needed relief from the heat there were lounges for talking or writing an open-air buffet under the trees for food or beer in the garden of the Arctic Institute of North America. The entertainment was magnificently organised All of 3000 guests were invited to cocktail or dinner parties given in the private homes of the hospitable medical community of the city Gay free-and-easy receptions were given to the congress by the Province of Quebec and by the City of Montreal, who gave two lavish evening parties in the chalet on top of Mount Royal. There were boat trips up and down the St Lawrence, fun fairs, a water ballet, and outings in the Laurentian Mountains. The wives went to fashion shows and on tours of Canadian industries including a brewery and were taken sight-seeing over Montreal by Trans Canada Airways.

At special convocations, honorary degrees were conferred on Prof W R. Hess, Sir Henry Dale O M., and Prof E Lundsgaard—all past presidents—by McGill University The Université de Montréal conferred degrees on Prof E D Adrian, O M and Prof L. Binet. Dr W W Francis director of McGill's Sir William Osler Library put on display the treasures of Osler's famous and unique historical collection, and the exhibit of early physiological books was particularly interesting

Officials of the International Council of Scientific Unions affiliated with UNESCO seized the opportunity to convene a constituent general assembly for organising an International Union of Physiological Sciences; and they also arranged a Symposium on the Future and Limitations of Physiological Research under the chairmanship of Professor Adrian

The amount of work presented at this congress was tremendous and much of it was clinical. The abstracts of communications were published in a 976 page book weighing nearly two pounds and containing over 1000 communications. Besides the official meetings demonstrations and films private group meetings were held for specialists in various subjects

Ten Russian physiologists headed by K M Bykov, attended the meeting Everyone was pleased to see that they mingled more freely with the other delegates than they did at the Copenhagen congress in 1950 They were neurophysiologists and in the main presented papers dealing with extensions of Pavlov's work These were given in Russian but they had brought with them translations of their communications in English and in French which were available to members of the congress Perusal of these papers and the abstracts shows that a tremendous amount of extremely interesting work on conditioned reflexes is being done in Russia Unfortunately, experiments and data are obscured by unnecessary polemics related to the deification of I P Pavlov, the conceptions of dialectic materialism, and the wickedness of Sherrington Fulton Magnus and Liddell It is a pity that in 1950 and 1953 we had only a small peek at a segment of Russian physiology No doubt they consider Pavlovian neurophysiology their most important contribution, but it is getting rather tiresome to those of us interested in other aspects of health and disease It would be nice if in 1956 we were allowed a peek at other aspects of Russian physiology such as studies on shock hæmorrhage blood coagulation, geriatrics and the physiology of cold—fields of endeavour in which Russian physiology presumably excels.

The symposia on Insulin, Hæmodynamics in Small Vessels Cardiac and Pulmonary Reflexes, Postural Mechanisms Physiology of Learning Formation of Thyroid Hormone and the Physiology of the Cold dealt in the main with reviews of published observations. Many of the individual communications were grouped together round specific subjects In some fields there have been tremendous advances or clarification in the past three years. Particularly impressive were the clarification of problems of blood coagulation and studies of the hyperglycæmic hormone from the pancreas—glucagon.

Elements in Wall of Blood vessels

A. C BURTON (Ontario) said that histological study shows four clearly defined types of tissue in the wall of blood vessels—namely the endothelial lining the various elastic tissue layers, the smooth muscle and the fibrous connective tissue which forms an outer tunic and penetrates between the last two tissues These elements are found in different proportions in the different types of blood vessels, and in the true capillaries only the first seems to be present Theoretical analysis with the aid of the classical law of LaPlace and indirect experimental evidence using the flow pressure relations in vascular beds, has given us a new appreciation of the rôle of each of these elements and their coöperation in the control of blood flow Semiquantitative estimates of the magnitude of the tensions developed in these tissues under the blood pressure and under vasomotor tone are now possible

Physiology and Pathology of Cerebral Cortex

K. M. BYKOV (Leningrad) stated that the three principles of I. P Pavlov's theory are determinism unity of analysis and synthesis, and unity of function and structure The physiologist and psychologist who follows Pavlov's teaching wages a relentless ideological struggle against representatives of metaphysical conceptions in physiology and psychology who, to date, are preaching dualism in the characteristics of processes taking place in the brain, contrasting the nervous process with the psychological, tearing it away from structure, denying to the nervous factor its main and determining rôle in all vegetative somatic processes, and attempting to restore an antiscientific subjective method of investigation Freud's idealistic conception, which has nothing in common with a scientific analysis of a normal or pathological disturbance of the activity of the functions of the central nervous system, is alien to the real physiology of the brain

Biochemical Observations on Inflammation in Rats

V W ADAMKIEWICZ (Montreal) said that a method was recently devised for studying inflammation in small laboratory animals This method—the "granuloma pouch" technique —is simple, and permits initiation of inflammation in an exactly reproducible and quantitative manner and production of large amounts of exudate which are well delimited by a considerable layer of granuloma tissue The exudate can be accurately measured and the granuloma weighed This technique does not cause much systemic stress since it is well tolerated even by hypophysectomised rats The exudate shows a high degree of constancy in its main chemical constituents within any experimental group hitherto investigated Using this technique, he studied the changes in various chemical components (proteins, sugars, fat, Na, K, Cl, P) in the exudate and granuloma when the course of inflammation was modified by hypophysectomy, adrenalectomy, treatment with prophlogistic hormones (corticotrophin, hydrocortisone, cortisone), and treatment with antiphlogistic hormones (deoxycortone acetate, somatotrophic hormone) Modifications in sugar and fat content were detected in the various exudates collected on the 14th day of inflammation Studies were also made on the permeability of the granuloma wall to ions (Na, K, Cl, P) and water during different stages of inflammation It was found that the granuloma wall is readily permeable to the ions. Finally, an attempt was made to show the triphasic nature of the response of the body to local injury The biochemical criteria used for this are the changes in concentration of Cl, P, Na, K, and the changes in water-clearances of connective tissue undergoing inflammation The triphasic nature of this "local adaptation syndrome" resembles that of the general adaptation syndrome

Incoagulable Afibrinogenæmic Blood

B ALEXANDER, R GOLDSTEIN, ANNE G LEBOLLOC'H, L K DIAMOND, and W BORGES (Boston, Mass) reported that studies on incoagulable blood from three subjects with congenital afibrinogenæmia have yielded information concerning basic aspects of the coagulation sequence independent of the fibrinogen fibrin system Immunochemical tests revealed at most only traces, and certainly less than 1% of normal, of fibrinogen or fibrinogen like material in the plasma After the blood is shed and exposed to glass, the earliest detectable changes, beginning within a few minutes, are morphologic alteration in the platelets and their progressive agglutination and lysis Almost in parallel, plasma antihæmophilic activity, originally normal, declines and practically disappears Also within minutes, Spca evolves from its precursor in normal manner Prothrombin disappears at normal velocity, or slightly faster than normal Ac globulin also disappears at normal rate The Ac globulin of afibrinogenæmic oxalated plasma is convertible to the active serum form by addition of thrombin Thrombin addition to the plasma also induces platelet agglutination, but this does not occur when thrombin is mixed with platelets alone Antithrombic activity of afibrinogenæmic plasma is normal The co factor of heparin antithrombin effect was demonstrable Quantitative data relating the fibrinogen concentration with the prothrombin time were obtained It may be concluded with reasonable certainty that conversion of fibrinogen to fibrin plays no rôle in the changes described above

Contractility of Human Uterus

H ALVAREZ and R CALDEYRO BARCIA (Montevideo) described studies of the pressure exerted by the uterine muscle on its contents, by recording the pressure of the amniotic fluid The coördination of the contraction is analysed by recording the intramuscular pressure in several parts of the by means of 4 microballoons inserted in the mass of the muscle and connected with a capacity manome During pregnancy localised contractions are produced th cause small and rhythmical oscillations in the amn pressure Sporadically a general contraction of the wh uterus appears In the days preceding labour the frequen of the generalised contractions increases progressively, w the number of the localised contractions decreases In norm labour there are generalised contractions which start fr the uterine end of one of the fallopian tubes, and spr very rapidly inwards and downwards (descending propa tion), all parts of the uterus contract with good synchro sation. The upper parts of the uterus contract stronger longer than the lower parts There are 3–5 contractions 10 minutes In the third stage of labour the record of t placental blood-pressure shows that the contractions ha the same characteristics as in the first and second stag though they are absolutely painless In the hours th follow labour, there is a progressive decrease in the of the contractions, and also in the propagation speed the contraction wave In abnormal labours the are observed (1) weak contractions, (2) bad coördinati with (*a*) lack of fundal dominance, (*b*) ascendent propagati of the contractions, (c) lack of synchronisation between t different parts, (*d*) localised contractions, and (3) hyperto produced by (*a*) over distension of the uterus, (*b*) asynchr nism, (c) high frequency of contractions (*d*) premat separation of the placenta

Physiological Responses to Aldrin

W. L BALL, K KAY, M CREVIER, and J W S (Ottawa) said that the possible ill effects on human bei of the recent tremendous increase in the use of chlorinat hydrocarbon insecticides is causing concern Aldrin w selected for investigation because it is the most toxic of common insecticides of this type In the preliminary st of the work it was demonstrated that it has growth stimula and œstrus inhibiting factors and causes organ enlargem and pathological changes A lowering of the basal meta lism and an increase in the serum esterase activity w observed All these effects occurred at dietary levels wh could result from the persistence of aldrin on foodst The rise in serum esterase caused by aldrin suggested it m antagonise the effect of the cholinesterase inhibitors. I pre-treatment of rats with aldrin produces fivefold protect against the organic phosphate insecticide, parathion

Sodium Excretion with Cardiac Disease

A C BARGER, R S ROSS, H L PRICE, G M. W and L BROOKS (Boston, Mass) investigated the ability excrete an infused load of isotonic sodium chloride in d with various experimentally produced valvular lesions of t heart In these animals the excretion of sodium chlo and water during the 8 hours immediately following a stand infusion is reduced to as low as 1% of preoperative con values Delayed excretion of sodium loads ac changes of cardiac function which produce little or no elevat of resting venous pressure, and no significant change in t ratio of infused sodium load to total exchangeable bo sodium was found

Carbohydrate Metabolism in Spinal-cord Injury

J M BERNSOHN, BROWN, and J R FINKLE (Hines Chicago, Illinois), studying the regulatory defects occurr in spinal cord injury, determined glucose tolerance curve 86 patients with spinal cord lesions at various levels, and a minimum of 15 months' duration. The results indic that while no differences in the fasting level were appar patients with spinal cord lesions in the cervical reg exhibited sustained high curves Statistical analysis of t results indicated that after the 30 minute period the va obtained in the cervical cases were all significantly hig than the other comparable values While the mechanism this dysregulation in carbohydrate metabolism is not c clusively demonstrated by the data, the results support concept that descending fibres from higher centres interrupted, and that this interruption may cause a function in the homœostatic mechanism involving the co of blood glucose levels

Goitre Prophylaxis with Iodised Salt

B E BRUSH (Detroit, Michigan) said that in 1923 a su of the school children in four Michigan counties, mad e State health department and the State medical society vealed that of 65,637 students 38·0% had goitre At the me of the goitre survey the amount of iodine in the soil d drinking water at various points throughout these unties was studied A close and constant relationship as noted in each instance in that the prevalence of goitre as in inverse proportion to the available iodine Following is, an extensive programme was begun to advertise the portance of iodised salt, which was placed on the market 1924 Subsequent surveys showed a remarkable decrease the prevalence of goitre in these same areas. In 1928 the er all prevalence was 9 0% and in 1951 only 1 4%. A record as made in these subsequent surveys of the number using dised salt, those not using it and those who used it part the time As was to be expected, there was a marked crease in goitre among those who had used iodised salt gularly and no decrease in those not using it

Metabolic Effects of Pituitary Growth hormone

A. Carballeira, H Elrick K R Mackenzie, and S L. Browne (Montreal) said that purified preparations pituitary growth hormone have been ineffective in man contrast to the striking metabolic effects produced in boratory animals. As these preparations have been adminis red either subcutaneously or intramuscularly with the ssibility of inactivation by tissue enzymes, the intravenous ute was chosen in these experiments. Under the influence growth hormone the rate of disappearance of injected mino-acids from the blood was accelerated. Urinary amino itrogen excretion was reduced in the growth hormone periments. The blood non protein nitrogen levels did not crease suggesting an incorporation of the amino acids into e tissues. A slight and transient rise in blood sugar levels as observed within the first 2 hours after the growth hormone as administered. The ketohæmia of fasting was also creased when growth hormone was used Serum phos-horus, alkaline phosphatase and urinary phosphorus owed no consistent change Eosinopenia was observed ith a dose of 3 mg per kg body weight but no significant anges occurred with the lower doses when compared with e control experiment Apart from nausea and vomiting, hich occurred in two subjects receiving the 3 mg per kg se, there were no untoward effects from the administration this preparation of growth hormone

Glucagon

C de Duve and C. A. Vuylsteke (Louvain, Belgium) id that glucagon (hyperglycæmic glycogenolytic factor of e pancreas) has been isolated with approximately tenfold rification from alkali inactivated insulin but has never en successfully separated from the native hormone In der to follow accurately the results of chemical fractiona ons, the assay on isolated rabbit-liver slices developed by therland and de Duve has been improved mainly by the clusion of a reference standard in the test and by the use logarithmically spaced doses, rendering the results amenable statistical analysis. By means of sodium-chloride frac-onation at pH 1·4 followed by fractional crystallisation, it s been possible to isolate preparations which have about n times the specific activity of the purest samples obtained Sutherland and co workers. Unfortunately the yields e small.

Toxicity of Serum and Urine

R Fischer (Regina, Saskatchewan) has tested the serum d urine of acute schizophrenics on larvæ of *Xenopus lævis* ed at 20°C; 10–20 ml per litre of serum or 25–60 ml per re of urine added to the water milieu of 14-day-old larvæ used a significantly higher mortality than the serum and ine of healthy controls in the same dilutions. Spontaneous mission or successful treatments gradually diminish the xicity to normal values Whether the toxicity of acute hizophrenic serum may be regarded as a consequence of e schizophrenic stress situation or might be in some way volved in the ætiology of schizophrenic psychopathology is ll uncertain.

Physiological Secretion of Glucagon

I P Foa Harriet R. Weinstein E. B Magid M. D ardman and J A. Smith (Chicago) investigated the hypo-esis that glucagon is a second hormone normally secreted the pancreas, by cross circulation of the pancreato-duodenal in of a donor dog with a femoral vein of a recipient dog jection of insulin in the donor dog was followed by hyperglycæmia in the recipient dog suggesting that the donor dog secreted glucagon in response to insulin hypoglycæmia The injection of glucagon into the donor dog was followed by hypoglycæmia in the other dog suggesting that the pancreas of the donor dog secreted insulin in response to glucagon hyperglycæmia These workers believe that secretion of glucagon is regulated by the blood-sugar level Their data indicate that pituitary growth hormone causes hyperglycæmia by stimulating the secretion of glucagon. This may explain, in part the diabetogenic action of growth hormone

Furadantin in Urinary Proteus Infections

C E Friedgood and D B Ripstein (New York) remarked that urinary tract infections due to proteus have been completely refractory to all forms of therapy Furadantin, a new broad-spectrum antibacterial nitrofuran has been found to be effective against proteus A group of 92 patients with pyuria due to either cystitis or pyelonephritis were selected in whom the infecting organism was proteus They had all had intensive antibiotic therapy which was unsuccessful. The patients were then placed on divided oral furadantin therapy four times a day The acute cases showed a remarkable response to the drug with 90% cures within one week. The chronic group of cases had a lower cure rate of approximately 65% sterile urine cultures The only side reaction was nausea. There was no evidence of sensitisation.

Liver Factor in Cerebral Metabolism

A J Geiger and J Dobkin (Jerusalem) reported that the brain when perfused with simplified blood' consisting of well washed erythrocytes in albumin Ringer solution ceased to take up glucose and to oxidise carbohydrates, but regained these functions on addition of a liver extract After about 45 minutes of perfusion with simplified blood when the brain ceased to take up glucose an endogenous substance presumably not a carbohydrate, was utilised During an hour's perfusion the non protein nitrogen in the brain increased from 60 to 160 mg %, the amino N remaining around 40 mg % After an hour of perfusion mannose is easily taken up by the brain but not glucose 40 minutes of perfusion usually reduced the glucose content of the brain to 30% of the blood glucose concentration, suggesting that all the glucose was in the extracellular spaces During longer perfusion a further reduction of this relationship indicated the impermeability of the whole brain to glucose Lactic acid accumulated in the brain up to 300 mg %. Inclusion of the liver in the perfusion normalised the brain blood glucose relationship and reduced the lactate concentration Glucosamine added to the simplified blood was taken up by the brain at a rate of 3–4 mg per 100 g per min. at a concentration difference of 100 mg., even 60 min after the start of perfusion Part of the glucosamine was esterified in the brain. Its concentration in the blood diminished progressively indicating utilisation in the brain immediately after the addition of glucosamine Lactate diminished but increased again as more glucosamine was taken up

Myocardial Metabolism

W T Goodale (Boston, Mass.) R. E. Olson (Pittsburg) and D B Hackel (Cleveland Ohio) discussed contrasting patterns of myocardial metabolism in diabetes, in cardiac failure and after insulin administration in man. Previously reported coronary catheterisation studies in dogs and man have shown excellent correlation between myocardial respiratory quotient and myocardial carbohydrate utilisation. In mild diabetes, the fasting R.Q was 0 7 with markedly reduced or negligible myocardial glucose lactate and pyruvate extractions despite high circulating levels. The glucose utilisation threshold was elevated to 95–260 mg per 100 ml Insulin restored this threshold to normal or below with marked rises in R.Q to 1 1–1 2 and with normal or high utilisation of all three metabolites. These findings tended to confirm the rôle of insulin in converting carbohydrate to fat. Although diabetes caused defective myocardial carbohydrate utilisation there was no interference with mechanical work or efficiency Patients with cardiac failure due to valvular disease with reduced effective work and efficiency showed normal lactate and pyruvate and superabundant myocardial glucose extractions, relative to both arterial substrate levels and simultaneous oxygen extraction This unaccountable glucose extraction for non-oxidative purposes is also seen in myocardial tissue slices and other preparations with limited survival time There is no evidence for anaerobic glucose metabolism nor for myocardial lactate production in the failing heart in vivo Cardiac failure of this variety thus cannot be related to myocardial anoxia nor to a failure in energy production, but rather to a failure of conversion of chemical energy to effective mechanical work Paradoxically, the diabetic heart, with limited production of energy from carbohydrate even in mild cases, remains mechanically efficient with energy derived almost entirely from other substrates such as fat

Photography of Pelvic Organs

H. S **Guterman** and M R **Cohen** (Chicago) described a pelvic photoscope, developed by Dr Guterman, for the visualisation and photography of the surfaces of the structures of reproduction in the human female Colour photographs can be taken of anatomical changes observed in these structures during the menstrual cycle, and it is possible to correlate anatomical, physiological, and endocrinological changes in the same individual during a given time

Metachromatic Activity of Urine

L B **Jaques**, E **Napke**, and S W **Levy** (Saskatoon, Saskatchewan) had injected heparin in animals and man, and measured the metachromatic activity of the urine By quantitative precipitation of urine with benzidine, metachromatic activity equivalent to 2–13% of the heparin injected was recovered This contained an excretion product of heparin, uroheparin, with metachromatic activity and low antithrombic activity Following the injection of heparin, depending on the dose, the anticoagulant may be (1) destroyed by heparinase, (2) degraded to uroheparin, (3) excreted unchanged In the case of (2) and (3) metachromatic activity is found in the urine

Early Ontogenesis of Higher Nervous Activity

N I. **Kasatkin** (Moscow) said that an important way of investigating higher nervous activity in man is the study of its development in a child, beginning at the earliest age This method, together with the clinical method, is the most fruitful and makes it possible to follow the highly complex process of development of the main mechanisms of higher nervous activity, starting with its most elementary forms The advantage of studying the higher nervous activity during the first stages of the development of a child lies primarily in the fact that a newborn baby possesses only a limited fund of unconditioned activities. Subsequently, on the basis of unconditioned reflexes, very complex systems of conditioned reflexes are formed in a child, which in their turn influence and modify the unconditioned activity An experimental *investigation of the development of the higher* nervous activity in a child made necessary the elaboration of a method for its study A method of motor food, protective, and orientative conditioned reflexes has been worked out, on the basis of which conditioned reflexes from all analysers may be formed in a child during the first months of its life The appearance of the first conditioned reflexes indicates unambiguously that the activity of the cerebral cortex in a child has begun The formation of early conditioned reflexes obeys definite laws The first such reflexes to appear are noticed about the middle of the first month of life , the order in which conditioned reflexes appear depends on the analyser within whose limits they are formed , until the end of the first month of life conditioned reflexes, if they appear, are distinguished by their extreme instability The second month of the life of a child is an age when conditioned reflexes may be created within the limits of all main analysers A conditioned reflex, in the process of its formation passes through several stages In children born prematurely by one or two months, conditioned reflexes to auditory stimulation may be formed at the same age as in children born normally Ontogenetical investigation of the higher nervous activity of a child makes it possible to elucidate the most important laws governing the early ages of its development These laws, established by a strictly objective method, must form a sound physiological basis for the care and upbringing of small children

Cholesterol Metabolism and Diet

A **Keys** (Minneapolis) said that studies on physically healthy men on controlled experimental diets show that (1) addition or removal of dietary cholesterol is with effect on serum cholesterol , (2) serum cholesterol is u in severe calorie undernutrition , (3) serum-cholest increases during active weight gain, when only carbohy is added to the diet to produce overnutrition , (4) in balance, change in the proportion of calories supplied dietary fats produces parallel changes in the total cholesterol concentration in a few days, a new plateau established in a few weeks Both vegetable and an fats are effective Studies on population samples of phys healthy men habitually on diets differing in the propor of calories supplied by fats in England, Spain, Italy, and United States show

1 There is no important influence of dietary fat level serum-cholesterol from age 18 to the early 30s

2 There is an increasingly marked effect from the ea 30s into middle age 50 year old men on high fat di as in the U S A , have a mean serum cholesterol le some 50 mg per 100 ml higher than men of the same on diets where the dietary fats provide 20–25% of total calories, as in the general populations of Italy a Spain In upper class Spaniards on high fat diets t serum cholesterol is like that in the U S A

3 These population differences are not merely ref of total calories or relative obesity The Italians were fat as the American men and were fatter than the Engl men studied But calorie inadequacy combined with moderately low fat diet, as seen in poor Spaniards, associated with the lowest cholesterol values seen in age

4 There was no evidence for an effect of d cholesterol in these population comparisons. This with the finding in the U S.A that the individual cholesterol value is not correlated with habitual choles intake of the individual

Cortical Activities

P S **Kupalov** (Leningrad) said that the method conditioned reflexes permits a strictly objective physiolog study of simple nervous activity as well as of the most comp higher nervous activity which constitutes the normal na behaviour of animals The position of the animal in room becomes a positive conditioned stimulus if at moment when the animal occupies a definite place in the a stimulus is applied which has already become a c food stimulus After this when the experiment is repe the animal actively and spontaneously places itself in t very particular place of the room and all its motor acti becomes strictly determined Therefore there exist spa conditioned stimuli Experimental neuroses can be p even in such conditions when the behaviour of the is absolutely natural and the freedom of its motor acti is not hindered By combining different stimuli from environment, the motor activity of the animal, and the sp conditioned stimuli it is possible to work out a compl normal behaviour of the animal representing in itself unification of several conditioned reflexes into a single nerv activity Such complex conditioned reflexes have b designated "situation conditioned reflexes"

Drip-tube Feeding in Nephrosis

G T **Lewis** and J J **Griffitts** (Miami, Florida) d the effect of drip tube feeding on patients with n The material is administered by constant drip through plastic catheter inserted through the nose into the s or duodenum 3000 ml can be given in each 24-hour p and this provides protein split products equivalent to 1 of protein and approximately 3000 calories In nearly instance, œdema has disappeared within a few days follo the initiation of the régime and has not returned as lo the conditions were adhered to No claim is made that conditions responsible for the nephrotic state have corrected, but with this régime it is possible to mai the nephrotic patient indefinitely in a good nutritive and œdema free During this period, Nature has opportunity to correct the defect

Blood Coagulation

Jessica Lewis (Chapel Hill, North Carolina) dis prothrombin, proaccelerin, and proconvertin in coagulation Methods for the isolation of prot proconvertin, and proaccelerin from human plasma been developed, and the interaction of these mat e presence of tissue thromboplastin and calcium studied he methods employed in this study of isolated prothrombin oaccelerin, and proconvertin are also applicable to clinical stances of deficiencies of these coagulation factors. Thus e cause of a prolongation of the one stage prothrombin me (Quick test) can be readily identified if due to a ficiency of any of the three factors alone or in combination his is illustrated by representative tests on (a) congenital ypoproaccelerinæmia, (b) congenital hypoproconvertinæmia, d (c) mixed deficiencies associated with various clinical sease entities.

Ileostomal Steatorrhœa

D A. MacFadyen (Chicago) had obtained data from 4 bjects with surgical ileostomy on a standard analysed et for periods of four days each Fifteen months after a ior investigation under the same dietary and analytical nditions, one subject developed steatorrhœa with excretion 90–110 g of fat from an intake of 135 g The data show at calcium and phosphorus excretions were normal and e same on the occasion of steatorrhœa as on the earlier casion when there was no steatorrhœa The increase in tty-acid excretion about 45% of the total lipid excreted as accompanied by slight increases in excretion of potassium d magnesium and by a marked increase in sodium excretion om the usual amount of 50–75 m.eq a day to 110–150 m eq day The conclusion was drawn that under the conditions normal gastric secretion of hydrochloric acid and normal gestion of proteins, the digestion of fat in the small intestine accompanied after absorption of calcium chloride by rmation of sodium soaps and calcium phosphate sodium ing provided as bicarbonate from secretions into the testinal lumen according to the reaction $HA + NaHCO_3 =$ $aA + H_2CO_3$

Splanchnic Carbohydrate Balance

J D Myers, R F Kibler, W J Taylor L. W Hamrick L Engel, and E Werk (Durham North Carolina) said at the technique of hepatic venous catheterisation has lowed the measurement in unanæsthetised man, of hepatic nous glucose concentration. Thus the arterial hepatic nous glucose difference may be determined and when ultiplied by the corresponding hepatic blood flow which turn is estimated by bromsulphalein clearance the lanchnic glucose balance is obtained. In 60 control, sting human subjects, the arterial hepatic venous glucose fference was always negative and the splanchnic glucose oduction averaged 64 ± 3 1 mg per minute per sq m body-surface. Adrenaline pancreatic hyperglycæmic ctor and probably growth hormone all produce similar d prompt outpourings of glucose from the splanchnic ea with the production of hyperglycæmia Parenteral ucose abolishes splanchnic glucose output this effect is nulated by the response to small doses of insulin

Hypothermia

C. B Ripstein C E Friedgood and N Solomon rooklyn, New York) discussed hypothermia in cardiac rgery The production and maintenance of hypothermia s several applications in surgery At low body temperature e metabolic needs of tissue are greatly reduced and the art can be excluded from the circulation for fairly long riods without producing irreversible brain or cardiac mage The production of a controlled drop in temperature beneficial in hyperthermia accompanying severe sepsis, d the refrigeration technique has also been used to control tractable pain and to retard the growth of certain tumours. cent investigation has revealed that certain anti histamine ugs exert a thermoregulatory effect in warm blooded imals. One of these is dimethylaminopropyl N-chloro enothiazine HCl (Chlorpromazine) A technique of oducing hypothermia has been evolved using chlorpromazine conjunction with refrigeration blankets and cooling of the spired air With this method body temperature can be wered to 75–80 within 30–60 minutes, and the venæ cavæ n be clamped long enough to open the right atrium and close septal defect

Apocrine Sweat gland

W B Shelley and H J Hurley (Philadelphia) said that ere is a paucity of physiological data concerning the apocrine eat-gland in sharp contrast to the enormous body of owledge surrounding the eccrine sweat-gland. Recent perimental studies by them have indicated that the ocrine sweat gland activity may be divided into two phases: apocrine sweat secretion and apocrine sweating Ordinarily apocrine sweating is produced by emotional stimuli, but it may be readily induced by pharmacological measures (local or systemic adrenaline) or mechanical stimuli (stroking local pressure) Unlike the eccrine gland there is no response to acetylcholine and no inhibition by atropine In view of the fact that appropriate stimuli only empty the tiny apocrine gland and do not prompt any further secretion, the quantities of apocrine sweat which may appear on the skin at any given time are minute

Crystalline Glucagon

A Staub, L Sinn and O K. Behrens (Indianapolis) remarked that the hyperglycæmic activity first observable in certain pancreatic extracts and later found to accompany some insulin preparations has been termed glucagon by Murlin Recently they have been successful in isolating a unique crystalline substance from certain pancreatic materials The crystalline glucagon is unique in its high hyperglycæmic activity: 0 1 μg per kg administered intra venously to anæsthetised cats is sufficient to give a 30 mg rise in blood-sugar The properties of the crystals are sharply differentiated from those of insulin Crystallisation is in the isometric system the crystals appearing as well-defined dodecahedra Zinc is essentially absent Sulphur is present only to the extent of 0 6% and is accounted for largely by methionine Thus glucagon contains little or no cystine—an important component of insulin.

Nickel Metabolism

F W Sunderman and J F Kincaid (Philadelphia) discussed nickel metabolism following exposure to nickel carbonyl The concentrations of nickel in the blood and urine have been estimated in normal subjects and in individuals accidentally exposed to the fumes of nickel carbonyl. Administration of 2 3-dithiopropanol to critically ill subjects greatly increased the excretion of nickel in the urine For the prevention of acute poisoning the concentration of nickel carbonyl in air should be less than 3 parts per million for a period of less than 30 minutes.

Biochemical Abnormalities in Brain

D B Tower (Montreal) discussed biochemical abnormalities in epileptogenic cerebral cortex. It has been found that slices of epileptogenic cortex (sampled at operation on patients for focal cortical seizures) when incubated in bicarbonate-Ringer medium containing glucose and eserine fail to show the increase in their content of bound acetylcholine (ACh) observed in normal slices under these experimental conditions. This defect in ACh metabolism can be reproduced experimentally in slices of cortex from animals in which seizures have been induced by administration of methionine sulphoximine In none of these cases is there significant deviation from normal in production of free ACh. Addition of glutamine or asparagine (10 mM) to the incubation medium has been found to correct the impairment of ACh binding in each instance but has no effect on ACh metabolism in normal slices. When slices of cortex are incubated under conditions promoting normal ACh metabolism both the glutamine and glutamic acid content of the slices increase during incubation with no loss of either to the medium. With slices of epileptogenic cortex (human or animal) and with slices incubated under lowered oxygen tension the glutamic acid content of the slices fails to increase and glutamine may be lost to the medium during incubation. The addition of adenosine triphosphate (3 mM) or asparagine (10 mM) to the incubation medium under these circumstances will correct the defects in glutamine and glutamic acid metabolism.

Darmstoff

W Vogt (Frankfurt Germany) discussed *Darmstoff*—a smooth muscle-stimulating biogenic organic compound It was always found in the wall of the small intestine of all species under investigation, also in the stomach and the large intestine but hardly at all in skeletal muscle. It stimulates the intestine uterus, and bladder The action is not inhibited by atropine or ganglionic blockers *Darmstoff* is an acid, which in free form is only slightly soluble in water but is readily soluble in many organic solvents. Since it is not destroyed by trypsin there is no indication of a peptidic structure. By its acidic behaviour *Darmstoff* can be distinguished from choline, histamine and enteramine Bradykinin kallidin and substance P are different from *Darmstoff* as regards their being destroyed by trypsin Moreover, substance P is markedly basic in nature (according to their recent investigations) The only substance being an acid like *Darmstoff* is prostaglandin For the moment it is not known whether these two substances are related

Experimental Hypertension

G E WAKERLIN (Chicago) discussed treatment of experimental hypertension with renin and antirenin Chronic experimental renal hypertension in dogs has been successfully treated with crude and semi purified hog renins, and chronic experimental renal hypertension in dogs has been prevented by prophylaxis with crude and semi purified hog renins These therapeutic and prophylactic effects are well correlated with the antirenin titre This evidence of antirenin (or an antibody to a protein closely related to renin) as the mechanism of the antihypertensive effect of hog renin constitutes support for the primary rôle of renin (or some closely related protein) in the pathogenesis of experimental renal hypertension Spontaneous (essential ?) hypertension in the dog has been successfully treated with semi purified hog renin, the antihypertensive effect being well correlated with the antirenin titre Obviously, these findings are good evidence that this hypertension is on a renal, renin basis Since antirenin to hog renin does not neutralise monkey and human renins, studies aimed at altering the antigenicity of hog renin, so that the antirenin which it produces will neutralise monkey and human renin, are under way addition antirenin to human renin is being prepared goats and dogs, in order to study the possible pathoge rôle of the kidney in essential hypertension

Osmotic Pressure of Blood in Renal Papilla

H WIRZ (Basle) said that the kidney of the golden ha (*Mesocricetus auratus*) shows a long and thin papilla exte some millimetres beyond the hilus into the ureter part of the papilla can be exposed in vivo by dissecting ureter and part of the renal pelvis A quartz capi diameter 10–15 μ, was inserted in one of the papillary bl vessels, and small samples of blood (0 2–1 μg) were w drawn Immediately afterwards, equally small samples urine were collected from the tip of the papilla The fre points of both blood and urine were determined by a m cryoscopic method Urine concentrations ranged 0 30 osmol per litre up to 0 62 osmol per litre The osm pressure of the capillary blood was either the same or most, 0 03 osmol per litre higher than that of the c urine This indicates that the whole of the extrac fluid in the papilla is strongly hypertonic when the k produces a hypertonic urine The results give substa support to the theory, advanced by Wirz, Hargitay, Huhn, that a hairpin countercurrent system provided by loop of Henle is involved in the process of concentrating urine

POLIOMYELITIS IN DENMARK
IMPRESSIONS FROM BLEGDAM HOSPITAL, COPENHAGEN

C A PALLIS
M.A B.M Oxfd, M R C P
SENIOR NEUROLOGICAL REGISTRAR, CARDIFF ROYAL INFIRMARY

THE 1952 poliomyelitis epidemic in Denmark, in which respiratory complications were prominent, has attracted much attention in this country, and many have visited Blegdam Hospital, Copenhagen, where Lassen [1] introluced the treatment of respiratory insufficiency by early racheotomy with insertion of a tightly fitting rubber uff tube, combined with bag ventilation, repeated aspiration and bronchoscopy, postural drainage, and the use of a stomach tube

At this hospital there remain a residue of "respiratory cripples," who provide dramatic proof of the severity of the outbreak In comparing the relative severity of different outbreaks of poliomyelitis, the number of cases requiring assistance with respiration in the acute stage is often misleading, since this gives no guide to the duration of the respiratory insufficiency A more precise guide might be obtained from the number of patients still requiring artificial respiration at various intervals after the acute illness, and this number would also give some idea of the amount of respiratory assistance required Such figures are available from Blegdam Hospital

WARD IMPRESSIONS

At this hospital chronic "respiratory" cases are nursed in a single block, in small wards with 3–8 beds Patients are transferred from isolation cubicles to this "chronic" block once the diagnosis is firmly established and the acute phase of the illness is over (The present policy is to perform tracheotomy, if judged necessary, while the patient is still in the isolation block, but at the height of the epidemic, when over 40 cases were being admitted daily, administrative niceties had to be waived and tracheotomy done wherever convenient) The patients usually remain in the "respiratory block" for several months In this block some patients are more or less amb others are totally tetra but all

require some help with breathing When the p are no longer in need of such help they are mo other parts of the hospital

The wards with chronic "respiratory" cases remarkable sight One is immediately struck by fact that, by day at least, they seem to contain ful many auxiliaries as patients The buildings are however, and nurses, relays of "ventilating" stude and physiotherapists do not seem to get in each way To each is assigned a precise function, and proceed methodically and with the quiet efficiency well established routine There is a constant noise from the asynchronous clicking and sighing mechanical positive-pressure respirators

In the acute stages of the disease a special nu detailed to each patient, but now each nurse copes with two, or sometimes three, patients One main duties is to deal with the secretions that accumulate in the larger bronchi The patients selves usually become quickly aware of these and localise them with remarkable accuracy Wheth rhonchus is palpable or not, the nurse vigorously p the appropriate part of the chest and immedi passes a suction catheter through the endotracheal or silver cannula The patients do not seem to mind and impressive amounts of secretion, that canno coughed up, are disposed of in this way This m may have to be repeated up to once an hour larger wards at least, one is sure always to see this applied to some patient or other

The nurse is often one of the first to recognise imp expansion of one part of the lung, and this is diately reported, if necessary verified radiographica and dealt with Anyone who has tried to d pulmonary collapse early, when the patient is nursed in a tank respirator, or who has struggled with problem of trying to examine radiographically patient (often capable, at most, of only a mini so of spontaneous breathing) will appreciate infinitely easier is this investigation when the pati "accessible" and when adequate ventilation maintained throughout My recollection of such tions when the patient was not accessible in this is that they were often veritable nightmares The had to be disengaged if the patient was to be over and the lung bases examined The exam commonly had to be extremely cursory, and the total ventilation often made it difficult to detect of diminished air entry Positioning of radiogr ates and centring of tubes were likewise hurried and en erratic. Occasionally the patient would go black the course of the examination and have to be ecipitately restored to the tank.

---

[1] ssen. H

With the new method the treatment of pressure ints is also much easier, for the back can be attended often and thoroughly I saw next to no bedsores at egdam Hospital even though many patients were tally tetraplegic and some were but skin and bone chnically, this is a remarkable achievement This all in striking contrast to the chaotic few minutes ring which the severely affected patient can be kept t of a tank respirator then the back may have to be tended to at the same time as another nurse is adminis ring an enema or giving an injection, and while the octor is attempting to examine the patient

Each patient receives physiotherapy repeatedly roughout the day Hot packs are applied even in ronic cases, before putting joints through their full nge of passive movements. Significant contracture is re even in patients tetraplegic for nearly a year The ght of totally wasted limbs some showing vasomotor ralyses, quite free of contracture was new to me This a triumph which reflects both the thoroughness of the ysiotherapist and the accessibility ' of the patient

Certain changes in the technique originally described Professor Lassen have been introduced over the past w months Air is gradually replacing the original ygen nitrogen mixtures open-circuit methods with rious ingenious types of expiratory valve are taking e place of the closed circuits with their soda lime nisters; and ventilation is now carried out at least often mechanically as by relays of students The ajority of patients I spoke to who had had experience both methods, preferred the machine —particu rly at night On the other hand most patients had eferred the students in the early stages of their sease when respiratory paralysis was complete morale ther shaky and fear of the implications of engine- ouble' very real. Some patients preferred the students r conversational reasons Some students were sociable mpanions others had mastered the technique of multaneous study and ventilation

There is a certain amount of misconception about the atient s ability to speak when treated by the Copenhagen ethod. The endotracheal tube is passed through a acheostomy and is therefore not in contact with the ocal cords It can be kept in this position much longer an when it is passed through the larynx without fear causing ulceration of the mucous membranes During e phase of bulbar palsy the air-cuff is kept blown up d thus acts as a hermetic seal, isolating the oropharynx om the trachea. Saliva cannot drown the patient ut neither can air pass up the other way and phonation therefore impossible This is only a transient phase owever most patients with bulbar palsy either die uickly or else recover soon Chronic bulbar palsy was ardly seen at all. Some patients retain the cuffed be (changed as necessary) for up to six weeks but the ajority for shorter periods. Once the patient can allow again the cuffed rubber tube is replaced by a lver tracheotomy cannula The patient can then eak intelligibly This is a big step forward and all o patients spoken to commented on the profound ychological effect it had had on them Other notable ates for the patient are those of the removal of the acheotomy cannula, the discontinuation of assisted uirasse) breathing and finally discharge from the respiratory block The various phases of rehabilita- on are somewhat reminiscent of the graduated régime a well run sanatorium

The atmosphere of the wards was one of genuine good eer with picture books and toys in the children s ards and games of chess, wireless and so on in the wards for adults Wards containing two or more Both respirators readily assume a sinister appearance but there was none of this here

RESIDUAL RESPIRATORY DISABILITIES

321 cases of poliomyelitis with respiratory trouble of one type or another were admitted to Blegdam Hospital following the adoption, late in August 1952 of the new method of tracheotomy and positive-pressure intratracheal ventilation; the vast majority were admitted during the months of September and October Of these patients 202 survived. 57% of the survivors still required assistance with breathing after a week, 40% after a month 28% after three months and about 20% after six months At the end of July 1953 29 patients (14% of the original 202) still required whole-time or part time artificial respiration One fact immediately emerges from these figures—that 'respiratory recoveries' are still occurring I was shown a case in which repeated fluoroscopy had shown paradoxical diaphragmatic movement for nearly six months after the onset of paralysis and where normal movements were beginning

Careful daily charts are kept of the maximum duration of continuous unassisted breathing each patient is capable of and also of the number of such attempts he is prepared to make in each twenty four hour period Many of the charts reveal delayed recoveries some partial, others more complete The patterns of respiratory recovery are varied. In some cases the duration of individual bouts of unassisted breathing slowly increases in others the patient gradually becomes capable of many more such bouts each day without significant change in the duration of each individual attempt

These facts challenge many widely prevalent views. If as the Danish figures suggest recovery of a diaphragm paralysed for several weeks is by no means exceptional then every effort must be made to keep the patient free of bedsores and contractures for as long as possible I have mentioned the success of the Danish methods in this respect. Perhaps we used to feel over here that contractures and bedsores were not fundamentally important, when the only prospect was several months in a tank respirator culminating in the merciful release of a terminal bronchopneumonia It may be argued that at Blegdam Hospital much intensive physiotherapy and nursing was 'wasted on some of the more hopeless cases. (This is a serious ethical problem of which our Danish colleagues are well aware) Other patients, however with less severely affected limbs, have without doubt benefited by the new method for when breathing returned, their limbs were in fair condition Few patients emerge from a tank respirator, after six months or more in a condition anything like as good as that of the Blegdam Hospital patients when their cannulæ are finally removed

29 patients still need ventilation There is clear gradation of respiratory crippling from very severe to minor requiring only a little help to ensure a peaceful night several of these patients are about to be "weaned ' Of the patients who had been in the block for more than six months 8 were incapable of even thirty minutes continuous unassisted breathing a further 8 could cope with periods of half an hour to five hours; and 13 managed spans of two or more hours The ' total spontaneous breathing time' per twenty four hour period showed a similar scatter 9 patients achieved summated breathing times of less than half an hour 9 times of one to twelve hours and 11 times of more than twelve hours

In these 29 cases associated paralyses were severe and at least 17 of the patients were tetraplegic. 'Tetraplegia here denotes not merely that a few muscle groups have been paralysed in each limb but that almost every anterior horn cell—from the upper cervical seg ments to the lower sacral—had been severely affected In many of these cases there is paralysis of the neck muscles with a "floppy head," severe diaphragmatic and intercostal paralysis, and paralysis of the dorsal and abdominal trunk muscles, in addition to virtually total paralysis of both arms and of both legs In the early stages many of these cases also had paralytic ileus and retention of urine I attended a necropsy of one such case, and the spinal cord and anterior roots showed a most striking appearance, there were no stones in the kidneys, and the lungs showed no gross changes The histological material accumulated at Blegdam Hospital in the course of the past few months promises to be most instructive

Of the 27 patients in hospital for seven months or more, 4 had proved renal calculi, 1 probably had calculus, 1 had an infected bladder and 1 had had hæmaturia Thus 7 (just under 25%) of this group of patients had urinary complications This is presumably the price of prolonged immobilisation, though it is difficult to see how it could have been avoided. Pathological fractures have occurred in 2 patients

My thanks are due to Dr J D Spillane for his help in arranging this visit, and to Prof H C A Lassen for his permission to comment on the patients under his care I should also like to thank the staff at Blegdam Hospital for their helpfulness

Medicine and the Law

Dentist and Anæsthetist

ON questions of professional liability to patients the Ministry of Health neither has nor professes to have any authority to declare the law It can, however, give guidance as advised by its legal staff

At a meeting on Sept 24 London Executive Council heard the Ministry's comments on a case in which the dental service committee had reported its opinion that there had been an unavoidable breach of a dentist's terms of service in connection with the administration of a general anæsthetic Although the fault lay primarily with the anæsthetist, the responsibility for the treatment of the patient nevertheless rested with the respondent dentist against whom a complaint had been made The dentist offered to forgo the fee paid to him in respect of an upper denture The dental service committee recommended that the offer be accepted, the executive council agreed and so also did the Ministry of Health to whom the report was communicated The Ministry, however, disagreed with the finding that there had been a breach of the terms of service "The Minister," it stated, "is advised by his lawyers that under the regulations the dentist is not responsible for the acts and omissions of the anæsthetist, and that any person who suffers injury at the hands of the anæsthetist should be left to his civil rights for a remedy"

The Ministry's statement appears to be right and reasonable Why should a dentist, any more than a surgeon, be responsible for what the anæsthetist does or does not do?

Transfer of Girl from Mental Hospital

The handling by the Home Office of the case of a 14 year old girl who has spent a year, latterly as a voluntary patient, at Hollymoor Mental Hospital, Birmingham has been sharply criticised by the chairman of the hospital management committee[1]

Last year the girl was found by a juvenile court to be in need of care and protection Five men were convicted of offences against her Last October, when she was said to have developed suicidal tendencies, she was transferred to Hollymoor Hospital from a remand home

In a statement issued on behalf of the hospital management committee, Mr. David Rhydderch, the ch said that the hospital authorities were informed on the morning of Sept 22 that the Home Office intended transfer the girl to Shore Hill Classification Sch Warrington, on Sept 28 On Sept 23, however, the g father gave the statutory three days' notice that intended to remove the girl from the hospital The n day the juvenile court amended the original approv school order, bringing forward the date of transfer Sept 25 Mr. Rhydderch said

> "It may be asked where was the need for such comp synchronised timing arrangements We have a str feeling that this was necessary in order to avoid embarrassing consequences of the legal blunder made wh parental authority was reconferred We deplore t indifference and the neglect of the Home Office author which allowed this young girl to remain almost 12 among adult mental cases, in spite of repeated lette pleading for her transfer We also say that to transfer girl to a place as distant as Warrington is far from fair to t parents, who will be unable to visit because of the dist and expense of travel"

In a statement issued last Tuesday, the Home Off explained that this case had been under considerat since last April, when on medical advice measures w taken to secure the girl's transfer to an institution mental defectives By the end of August no vacan in an institution for mental defectives had been found the regional board, and in view of representatio the chairman of the Hollymoor Hospital Managem Committee and others, the case was reviewed In co quence the girl had been transferred to Warrington observation The statement pointed out that an or made in September, 1952, for the girl's detention Newfield School was still in force, but this had to endorsed for the Shaw School, Warrington

Public Health

Poliomyelitis

POLIOMYELITIS notifications (uncorrected) in Engl and Wales during the week ended Sept 19 (37th w of the year) were as follows paralytic 123 (92), n paralytic 104 (81), total 227 (173) This is an incre of 54 compared with the previous week, the figures which are in parentheses

This increase is largely accounted for by an increase notifications of 15 in Coventry and 14 in Kettering, both places there has been an abnormally high inc of the disease

Second Quarter in Scotland

In the three months ended, June 30 this year, birth-rate in Scotland[1] was 18 0 per 1000 popn which is 0 1 more than the rate for the co quarter of 1952 The number of stillbirths was equival to a rate of 24 per 1000 total births The death-rate in the corresponding quarter of 1952, was 11 2 per 1 population The infant-mortality rate was 29 per 1 live births, this rate is 5 below that for the c quarter of 1952, and is the lowest recorded for a quarter The death-rate from tuberculosis was (respiratory 22) per 100,000 population The former is 6 less than that for the corresponding quarter of 19 and the latter is 3 less, and these rates are 32 and below the five years' average

Fertility in 1931 and 1939

The last volume[2] in the series of decennial supplem to be issued in connection with the Census of 1931, published, analyses data on fertility in that year and 1939

In England Now

Running Commentary by Peripatetic Correspondents

IT is probably true that the activities of Mr William Illott have been on balance *beneficial to the country* nt in at least one household they have left a legacy of onfusion and despair We can never find the paragraph the papers which tells us whether to put the clocks rward or back and if we once falter in our empirical elief and sit down to argue the matter out we are retrievably lost. In fact, we have to get up unreasonbly early on Sunday morning to find out from the .B C whether or not we are two hours wrong

All this is of course, child s play to the Americans o recently attempted a journey by rail from Cincinnati Chicago, where we were to catch a plane We were esh and fit when we reached the travel agency and we ad a little notebook to take it all down in It was not ll we were immersed in schedules that we realised we ere travelling on the day summer-time reached Chicago ut not Cincinnati The young lady was most helpful e would leave Cincinnati on Eastern Standard Time ut at Chicago we would be on Central Standard Time that normally we would have to put our watch back n hour But then' she said, Chicago will be on ummer time, so you ll have to put it right on again ' Ve were immediately roused 'Well then we said *what time is the time we are due to arrive in Chicago* ritten in? Central Standard I guess said the oung lady doubtfully ' I don t know much about trains yself. She rummaged in the back of the schedule Yes, she said 'Central Standard So' we said raftily the train journey will actually take an hour onger than we think it will—or will it? The young dy smiled patiently You won t have to alter your atch, will you?' she said speaking slowly and dis inctly No, we replied thankfully 'Well then he said it will be an hour later than that time on our watch' 'We see' we said slowly (we really hought we did) "Then how long will we have in hicago till the plane leaves?' Ah, said the young dy in a businesslike fashion, ' planes are different. Ve'll have to see what time your airline is operating on Vhere did you say you were going?' We told her and he had begun to look it up when a thought struck her They'll be on Mountain Time, you know, she said and that means you'll have to put your watch back wo hours instead of one before you get there Unless, f course they're having summer time too

We staggered out our spirit broken. When the time ame we *turned up an hour too soon* at Cincinnati

* * *

We have just acquired a puppy of tender age and he as been installed in a box in the kitchen. The first w nights we had him he cried like a baby and refused bo comforted until he was taken upstairs and allowed crawl under the bedclothes of one of the junior members the household He wasn t cold he wasn't hungry he st wanted company in bed with him But we did not ceive an expensive physiological education for nothing, nd we have rigged him up a heart-lung preparation in s box for him to sleep with. It consists of a rubber ot water bottle on top of a ticking alarm-clock, and he eeps like the dead.

* * *

We thought that what was good enough for T E. awrence would be good enough for us, so the prepara ons for the expedition were put in hand and one sunny y we set out to follow the master s *footsteps* We chose canoe that was narrow and light—Canadian pattern o were told and rather unstable for the novice

The river was low and the current sluggish it being e hot season and we were able to make the upstream urney at a fast pace the canoe handling beautifully e had however to turn up a narrow tributary to the ght and were soon in the shallows and then completely ounded Stepping out into the now rapid current we uled the boat up over the flat stones into deeper iner water again and then paddled on ducking our ads to avoid the overhanging vegetation which by w almost closed over the whole width of the stream ll was still and as we rested on our paddles the silence seemed to close in on us and it was a relief to hear the splash of the water again Rounding a last bend to the right we found ourselves at the mouth of the tunnel which we found to be blocked by underwater debris over which the craft had to be carried Once this obstacle was passed we found to our relief that we were in deep water again. After about twenty yards the tunnel turned sharply to the left and we were in complete darkness soon to be pierced by the light of our torches. The walls of the tunnel were covered by a slippery brown alluvium but the air was cool and sweet and we made rapid progress. Faintly in the distance we heard the silvery tinkle of a small waterfall which seemed to call *us mysteriously on. But suddenly* with a *spine-chilling* scraping sound the canoe grounded We stepped out with some difficulty and pulled the boat forward into deep water again but on attempting to regain our seats we misjudged the slippery floor and the instability of the craft the latter turning over sinking and precipitating us completely into the black water Cushions socks shoes, paddles began to float away and we retrieved them with difficulty But the worst task was to raise the dead weight of the boat and hold it up over our heads to empty it. In the confined space the water poured all over us and when we finally sat down again we squelched miserably Thrice more we were grounded as the tunnel wound its sinuous way and the roof became alarmingly low However, we had learned how to get in and out of the canoe without tipping it over and the first horrifying mishap was not repeated We saw no animal life larger than small water-snails which covered the walls in great numbers and whose sharp-pointed shells were painful to the feet

After turning a last bend to the right we saw the bright light streaming through the exit ahead, and shooting through a hanging fringe of ivy leaved toadflax we were *out in the warm sunlight* and *scented air of the water* meadow The narrow canalised stream continued on between high banks overhung by dense bushes and trees and then suddenly widened out and entered the main river bringing us back to the streets of the town which we had toured by underground waterway

We were somewhat disappointed by the expedition Lawrence wrote of fast-rushing water gates closing the exit of the tunnel and the danger of being trapped by a sudden rise of water Maybe he chose the wrong season for his trip we certainly did—another six inches of water and we would have come through without mishap The obstacles which had been our undoing were piles of stones and bricks thrown down the inspection holes normally covered by heavy iron lids. It was up these same inspection shafts that Lawrence had discharged his revolver maybe the bricks and stones indicate retaliation by the surprised citizens of that time

The boatman seemed surprised at the water in the canoe until we told him that we had capsized I told you it was a wobbly one he said We could not but agree

* * *

Once again I ve got to face it. I haven't seen a child with a fish hook in its finger for a fortnight. The spate of Temporary Residents complaining of sunburn sand in ears and summer-diarrhœa is easing off. The Follies on the Parade have folded their tents. The shops are full of winter clothes fur lined gloves, and warm bootees Summer dresses are disappearing from the Front and swimming-suits are no longer there My spare time is occupied with bonfires of swept-up leaves. My nine November maternity cases, booked so lightheartedly in the early spring loom alarmingly near Patients cluster round for their anti-catarrhal vaccine; one even proudly displays her first crop of chilblains. I ve tried to ignore it, but winter will soon be here: the evenings are drawing in and as usual I don t like it.

* * *

To protect my consulting-suit during the washing up the children gave me an apron for my birthday It is a great success but I tend to keep away from windows, and feel that it might have been more appropriate for one of my surgical colleagues It is navy blue with white vertical stripes.

How Do I Treat My Doctor?
Very seldom.

Letters to the Editor

THE R M B F

SIR,—I shall be most grateful if you will spare space in your columns for me to appeal for donations to the Royal Medical Benevolent Fund to enable us to distribute Christmas gifts to beneficiaries of the fund

I hope that all members of the profession will contribute towards this extra help at Christmas time, for it is enormously appreciated by doctors and their dependants who have *fallen on hard times* The fact that they are remembered by their more fortunate colleagues gives the recipients of gifts even greater pleasure than the gifts themselves, which, however, provide extra comforts or small luxuries for which they have been longing

I ask subscribers to the Fund to spare a little more for this special purpose, and I beg others to become subscribers at the same time as they respond to my present appeal

Donations and subscriptions should be sent to the Secretary of the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S W 15, and marked "Christmas Gifts"

WEBB JOHNSON
President,
Royal Medical Benevolent Fund.

PREVENTION OF POLIOMYELITIS

SIR,—I have been very interested in the discussion in your columns following Dr Agerholm's stimulating article (Aug 8)

I agree wholeheartedly with her views on prevention of spread and necessary quarantine—although at present such measures cannot be fully applied except to school children, teachers, and food-handlers A great deal can be done by discouraging unnecessary movement of people from an infected area Every additional week that the disease is contained in a locality is a great gain in view of the comparatively short season of poliomyelitis.

Dr Agerholm's hypothesis that changes in the epidemiology of the disease are due to the recent importation of an immunogenically new virus deserves careful consideration She makes two main points in favour of this hypothesis

1 "The age incidence has altered " But this is no recent change, as is shown by the following extract from the annual report for 1911 of the medical officer of health for Cornwall "the disease has obviously changed its incidence, the average age of 50 consecutive cases being 6 years, which appears to be high for infantile paralysis even adults now frequently succumb to the disease"

2 "The proportion of symptomless infections appears to be greatly reduced, and multiple cases in a family or school have become relatively common" I assume that symptomless infections here means non paralytic cases

My experience in Cornwall has been that the ratio of paralytic to non-paralytic cases has varied in different years In 1947, and again in the present year, there has been a high proportion of non-paralytic cases, and of the paralytic cases few have been really severe, whereas in 1949 and 1950, when the incidence in the county was heavy, there was a high proportion of severe paralytic cases

Such a variation might well be due, as Dr Agerholm suggests, to a different virus being present in severe epidemic years I am uncertain whether there has been any increase in multiple cases of recent years The difficulty is that few outbreaks before 1946 were adequately documented, indeed, for much of our information we must return to the 1911 outbreak In this outbreak, Reece tells us (*Rep loc Govt Bd publ Hlth,* 1912), amongst the 154 cases which occurred in Devon and Cornwall, "in four instances there were two cases, in two there were three cases, in four there were f cases and in one instance, there were six cases in a hous It is evident, therefore, that the changes at pre apparent in the epidemiology of the disease have occur gradually and cannot be cited in support of the hypoth of the recent introduction of a new strain of virus.

Truro Cornwall E R HARGREAVE

SIR,—In the Silver Blaze mystery the pivotal fact Sherlock Holmes's mind was that the dog did not in the night, a negative clue in the mystery of incidence of poliomyelitis I suggest that attention has not been paid to the people who exposed to infection and do not get the disease. rural practitioners are familiar with the phenomenon two or three cases of poliomyelitis (or more comm of infective hepatitis) occurring in the same parish no obvious point of contact between them something remote like the handle of the village p office door or contact with a contact of a contact, are irresistibly forced to the conclusion that is widespread and susceptibles are rare. Indeed, several regions of the U S A four-fifths of the over 14 years of age were found to possess poliomye antibodies Bearing in mind the prodigious habits of viruses, the country general practitio realises that with one case in the village it is as if population of China had erupted into Lower Snor which makes Dr Agerholm's suggestion of herds of contacts a little impracticable But why not everyone get poliomyelitis? Individual resist the virulence of the organism, chance? From meagre experience in wandering round as a tenens I have a hunch that the main element in mining immunity is the presence of another virus protects the host, a jealous virus, sometimes strongly, sometimes weakly, the well-known faculty or gift for "interference" May I the scraps of experience that have led me to this

1 In the Auckland, New Zealand, epidemic years ago I was shown cases by Dr Sweet, the child specialist, who gloomily admitted that the disease was his Truby King fed children, his excessively hygienic babies

2 A boy of 11 in the junior school, attached to a public school, whose housemaster's baby had been sent to hospital with poliomyelitis the week before and the boy had actually touched, had a febrile illness pain in the neck as no 1 symptom for ten days. The spec said it was not poliomyelitis, on the insufficient ground there was no muscular weakness, but, of course, it But why did not his younger brother or some other at the school who must have been infected get any This is an ordinary experience, a textbook example of capricious incidence of poliomyelitis

3 I saw a youth of 19 in a Norfolk village who in of sore throats complained of sore throat On my visit he diagnosed himself "I am much better, but I lift my left arm" A few days later, a mile away and no obvious connection with this case, I saw a woman alone in an isolated house with three young children, two whom were on her bed Her chief complaint was pain the back, following "flu" I wired for her husband who on service and got the M O H to see her He was doubt but next morning before breakfast there was no doubt all She was sent to hospital where, tragically, she few days later in an "iron lung" But why did those ch escape? There can be no doubt about the virulence of organism here

4 In another county I was shown a girl who in a epidemic of poliomyelitis thought she had the disease, was labelled as "neurotic" on the somewhat ground that her brother was in a mental hospital. I measured her up and found she had muscular wasting sent her off for treatment This girl had limped a mile to see some friends or relations who had five small and I was called to see these, one after another, with peratures, pains in the back and legs, vomiting, and meningism all of which passed off in twenty four

ıg up the M O H but he seemed reluctant to play ball the idea that there could be five cases of poliomyelitis ıo household and being only a locum I let it pass. But could possibly be the deciding factor which allowed group of children to be infected and another group with ser contact with a known case to be spared ?

suggest that some very rewarding information ıt be gathered—especially by the field naturalists of icine, the rural practitioners—by inquiring into what mon virus diseases people who get poliomyelitis not had and close contacts who do not get it had Personally my guess is that the villain or or hero of the piece is herpes simplex It is the most spread viral infection in man It is contracted in childhood and is kept as a slightly irritable pet ughout life Adults do not get it but, of course periodically display their childhood s infestation ıet and Williams found that 93% of hospital patients antibody in their blood but only 37% of the more enically brought up university graduates Over are infected and remain carriers for life' says of the authors of that mine of information *Virus Rickettsial Disease* In short I suspect that herpes lex negatives are liable to become poliomyelitis s. I suggest that there is a prima facie case for stigation, which I understand has not been made in words that Holmes himself might have used us herpes simplex follow, my dear Watson, may be man.'

URINARY EXCRETION OF CITRATE

SIR,—The interesting preliminary communication last week by Dr Fourman and Dr Robinson shows that a decrease of urinary citrate clearance may be associated with experimental potassium depletion in man but there is no definite proof that this is directly due to the potassium loss The clearance of citrate by the kidney is a very complex process since urinary citrate as measured chemically consists of at least three different fractions—i e. dissociated citrate anions balanced by sodium or potassium, undissociated citric acid itself and un ionised calcium citrate chelation complex. Gamble[1] has shown that the degree of dissociation is governed by the urinary pH and Hastings et al[2] have studied the effect of citrate as a calcium chelating agent. As will be seen there is reason to believe that these three moieties are handled differently by the renal tubules

The renal clearance of citrate is greatly modified by at least five distinct factors (*a*) plasma level of citrate, (*b*) pH of the urine (*c*) calcium content of the urine (*d*) œstrogenic and androgenic steroids, and (*e*) presence of urinary infection

(*a*) Like most other substances reabsorbed by the tubules from the glomerular filtrate the citrate clearance increases with rising plasma levels

(*b*) Free citric acid appears to be reabsorbed preferentially to citrate ion, and therefore the citrate clearance increases as the urinary pH rises.[3, 4]

(*c*) Calcium citrate chelation complex is less well reabsorbed and therefore the citrate clearance increases with a rise of urinary calcium[5]

(*d*) Œstrogens specifically increase and androgens decrease the renal citrate clearance by a direct action on the renal tubules[4] This is of little practical importance in the male but accounts for the wide cyclical fluctuation of citrate excretion in the female during the menstrual cycle[6]

(*e*) Urinary infection diminishes citrate clearance since citrate is rapidly destroyed by many bacteria in the bladder and the renal pelves as well as in stored urine[7]

In the course of an investigation on calcium metabolism,[8] all these facts were confirmed but no new information was elicited In the data presented by Fourman and Robinson it seems that the effect of variation of calcium content of the urine may have some bearing on the fall of citrate clearance observed It is virtually impossible to produce an absolutely pure uncomplicated potassium depletion in man In the method described by Fourman[9] there is a complicating acidosis due to the use of a sulphonic resin in the ammonium cycle and also there is preferential absorption by resin of divalent cations in the gut with a consequent reduction in calcium and magnesium intake Hypocalcæmia and tetany have been reported after relatively short periods of therapy with the sulphonic forms of cation exchangers[10] and urinary calcium usually drops very rapidly with ingestion of such resins In experimental potassium depletion studied by Black and Milne[11]

which differed from the method of Fourman in that a resin in the sodium cycle was used in the pre treatment of the diet, the calcium content of my own urine dropped sharply from 53 to 5 m eq per day during the depletion period I have confirmed the correlation between calcium and citrate excretion in my own case,[8] the correlation coefficient being $+ 0.92$ at ordinary urinary pH range The regression equation of citrate to calcium was of the formula $y = 0.85x + 0.2$ where y is citrate excretion in mg per minute and x is calcium excretion in the same units It is probable that the regression constants vary considerably from individual to individual Applying these results to the data on potassium depletion, I would have expected a fall of citrate excretion from 1180 mg per day to 370 mg per day *due to the effect of hypocalcuria alone* This is a greater fall than that recorded by Fourman and Robinson, but it must be admitted that the high-milk diet of our depletion experiment caused an abnormally high calcium excretion during the control period Studies of citrate excretion will in future be included in a research on potassium depletion at present in progress in these laboratories

If it is finally shown that potassium depletion has a direct effect on citrate clearance, it is still difficult to agree with Fourman and Robinson that this would probably be secondary to abnormal glucose metabolism with disturbance of the metabolic processes of the tricarboxylic acid cycle This should influence citrate clearance rather by alteration of plasma citrate levels than by a direct action on the kidney The publication in full of the data of Fourman and Robinson, with details of the effect of variations of calcium excretion, will be awaited with great interest

EXTERNAL CEPHALIC VERSION

SIR,—In reply to Mr Dalley's letter (Sept 12), I wish to point out that the two sets of figures he analyses are not comparable In forecasting the probable outcome of 1000 cases of breech presentation diagnosed during the course of pregnancy in the Middlesex Hospital, he forgets the number of successful versions which would result from version without anæsthesia, and it is in 80% of the remainder that version would be likely to succeed with the help of anæsthesia Thus the total number of cases in which version as a whole is likely to prove successful is necessarily much more than 80%, and will undoubtedly reduce the incidence of breech presentation in labour well below the 60 per 1000 estimated by Mr Dalley In fact our incidence of breech presentation in babies weighing more than 3.3 lb at birth was slightly below 16 per 1000 (corrected figure)

ACROPARÆSTHESIÆ IN THE CARPAL-TUNNEL SYNDROME

SIR,—I was very interested in the article on this subject by Dr Kremer and his colleagues (Sept 19), as I have dealt with quite a number of these cases by operation The procedure adopted by me has, however, been a more extensive exploration through a vertical incision, which included examination of the flexor tendons and their sheath as well as the flexor retinaculum The vertical incision has never caused any contracture, and the median nerve has never become adherent to the scar

With this more extensive exploration the flexor tendons are seen to be enveloped in œdematous synovial membrane, this œdema, which is often severe, resembles, though it is more extensive than, that seen in tenovaginitis stenosans of the short extensor and long abductor tendons of the thumb I contend that this condition called acroparæsthesiæ in the carpal-tu syndrome is a tenovaginitis stenosans involving flexor tendons as they pass under the flexor retinac In this particular instance, it is complicated b passage of the median nerve through the same tu the tendons The nerve, being the more delicate ture, gives rise to earlier and distinct symptoms.

The treatment is the same as for tenovaginitis sten elsewhere—i e , division of the tight constr band

"COIN" LESIONS OF THE LUNGS

SIR,—Your annotation of Sept 19 indicates the r which any person who "believes himself to be in health" may run if he submits himself to mass graphy, for it tells us that if his radiograph show shadow of a small healed localised lesion he ma induced to submit in turn to multiple radiogra examinations, tomography, angiocardiography, r active isotopes, bronchoscopy, and biopsy

"When all these investigations have been comp however, the answer is very often still in doubt The place for these lesions is in the hands of the pathologist it is probably wiser to remove them all, tuberculous and tuberculous, except perhaps in patients under the age o in whom the shadow lies at the apex of a lobe"

On this principle would it not be logical to rem lung as soon as you see a shadow on the radiog This would surely save our overworked radiolo biochemists, pathologists, anæsthetists, and all technical and nursing staffs—yes and the a great deal of labour Speaking of the alternative p of "waiting, watching, and operating only if the enlarges or excavates," you say that "in view of safety of modern surgery this course is s justified" Is even anæsthesia always administ without risk?

In Storey et al 's series, of 40 patients (mostly h young men on active service) in whom a histo diagnosis was made, the lesion proved to be tuberc in 70% As a radiologist with extensive experienc chest work I should say that the majority of the 30% of "isolated, well-defined, spherical shadows" young Service patients with no symptoms were shad without the slightest clinical significance Patients h died after and during such investigations, and if had no symptoms before operation they have infrequently had them after it the mental disturb alone, can be serious Moreover, if the tuberculous is already healed its resection is unlikely to confe slightest benefit on the patient True, if left alo may break down, but, if that happens, a lesion w has healed once will probably do so again if the r of the patient is assisted Finally, have we any p that resection of a malignant lesion will cure the patie Are not the "successes" possibly due to errone interpretation of histological material? I have know patient diagnosed as having malignant disease live years after "mere biopsy" as the treatment, and have seen some spectacular radiographic lesions rem unchanged for as many and more years—until d followed attempts to remove them I have known resections for pneumonia

In the same issue of your journal Dr Bernard Le points out that medicine "has only slowly and pain won through to some sort of scientific basis" Is not fault in "some sort of scientific basis"? Dr Doml (Sept 5) and Dr Odlum (Sept 19) say that ther every need for reorientation in every branch of medi Recently a famous surgeon was quoted as saying

I advise the man who smokes heavily, especially if h over 40, to have a chest X ray every six months—or prefe

three months—so that the physician can find the
r if one develops while surgery can still cure it '

't from the truth that no-one has any right to claim
re would it not be wiser, if it can be proved that
ang is the certain cause, to prohibit smoking ? I
this though the radiologist, the physician, and the
eon would be deprived of work
is the theory of cellular pathology given us so much
that we need not consider ' reorientation ? It
s to me that the clinicians of the past learned more
bservation of the patient.

SUCCINYLCHOLINE CHLORIDE AND LIVER DAMAGE

R,—In his letter of July 11 Professor Macintosh
es that during his visit to India and Indonesia he
d that despite malnutrition and anæmia—and
umably ' liver damage —patients needed curare in
er doses than I had anticipated He also states that
ound that succinylcholine (Scoline ' Brevidil M)
aved in a similar manner
wo winters ago I spent the best part of three months
a lecture demonstration tour of Pakistan (East and
st) India, Ceylon Burma and Iraq and gained the
owing impressions :

avenous Anæsthetics

næsthetic drugs which are given intravenously and are
wn respiratory depressants had to be used with caution ;
rwise long periods of apnœa resulted. Many patients
ved marked muscular relaxation with what we in England
ld regard as modest doses of thiopentone ; for instance
H. Barat, anæsthetist at the Eden Hospital, Calcutta,
onstrated two anæsthetics for sterilisation of female
ents using thiopentone alone (i.e without additional
lation anæsthesia) in doses of 11 5 ml. and 14 ml. respec
ly By and large I gained the impression that the dosage
hiopentone required (Pentothal or Intraval) was
ut two thirds of that which I had been accustomed to
ng at home in England. Postoperative respiratory depres-
was most marked when pethidine had been used during
ations (perhaps because it is detoxicated almost entirely
the liver) and great vigilance had to be observed to
ent morphine being given *as a routine* after operations
ad of being *withheld until the patient complained of*

cular Relaxants

xcept in Iraq *d* tubocurarine and gallamine (Flaxedil)
required in about two-thirds to four fifths of the dose
was accustomed to use in England Scoline was not
onstrated as it was thought inadvisable to demonstrate
rug which at that time was still in the experimental

al and Extradural Anæsthesia

wing no doubt to the patients shortness of stature spinal
sthesia could often be induced with surprisingly small
s. For instance in Colombo I achieved spinal anæsthesia
panhysterectomy using only 8 ml. of 1 in 1500 solution
Nupercaine Admittedly the injection was given in the
ng up position, but the patient was placed on her back
oon as the injection had been finished and the puncture
swabbed with iodine Skin analgesia rose to the level
bout the eighth thoracic segment I feel quite sure that
anæsthetists would stake money on achieving analgesia
to this height with such small doses given to an average patient in the British Isles. Iraqis needed doses similar to our own particularly if they came from Kurdistan Owing to the low salt intake and the prevalence of vegetarianism (with the consequent consumption of second-class proteins) blood pressures in the Indian subcontinent are rather low and anæsthetists there are in the habit of giving spinal anæsthesia to any patient with a systolic blood pressure above 100 mm Hg When used for cæsarean section I found that spinal anæsthesia caused a similar drop in blood pressure to that in English patients ; it was, however sometimes difficult to restore the blood pressure to normal by the use of vasopressors. In one instance—a Chinese patient in Rangoon—prophylactic ephedrine and doses of methylamphetamine (Methedrine) during the operation failed to prevent a dangerous fall of blood pressure intravenous noradrenaline did however bring the blood pressure back to normal Using lignocaine (Xylocaine) extradural anæsthesia (sacral extradural and spinal extradural) required much the same dosage as is used for patients in Europe and the U S.A

Resuscitant Drugs

The effect of thiopentone and pethidine could be reversed quite readily by nikethamide (and a similar experimental drug issued privately by Imperial Chemicals [Pharmaceuticals] Ltd) in the usual doses. Neostigmine (with atropine) proved an adequate antidote to *d* tubocurarine and gallamine

It is of course difficult to know what Professor Macintosh had in mind when he used the words larger doses than I anticipated ; and it may be that he found as I did that the dose of *d* tubocurarine and gallamine ranged around 70% of that used in England Again when using several intravenous agents each of which is a central or peripheral respiratory depressant *it is often difficult to judge which of these drugs is* responsible for any excessive apnœa—i e Professor Macintosh may have used smaller doses of thiopentone than I was using and therefore required larger doses of the curare drug to secure quiet respiration and muscular relaxation I would be interested to know whether Professor Macintosh agrees with me that intravenous anæsthesia must only be administered to Asian patients in cautious doses.

JUVENILE DELINQUENCY IN NORTH AMERICA

SIR,—In your article last week on this subject you state that it is rare in this country for a juvenile case to be heard in a criminal court What I assume you mean is that it is rare for a juvenile case to be heard in an adult court since all our juvenile courts are in fact criminal courts.

In this country the age of criminal responsibility is fixed at 8 years, which is much less than that fixed by any other country outside the British Commonwealth On the Continent it is generally 13 or 14 Children under that age some of whom would here be regarded as law breakers are dealt with by a child welfare organisation and not by any judicial process.

Our exceptionally low age of criminal responsibility is apt to strike foreign observers as both absurd and shocking and there are very real practical drawbacks to it Sometimes a child may appear before a juvenile court for whom some special treatment is clearly necessary but the magistrates may find their hands tied either because the evidence is not sufficient to prove the particular offence or because the police charge is not exactly in accordance with the facts Whatever steps they might like to take for the child s welfare they have no option but to dismiss the case

Another drawback of the status of our juvenile courts is that it leads to a hard and fast division between the treatment of the child labelled delinquent and the child labelled maladjusted, though as a matter of common sense such a division is meaningless So many maladjusted children are delinquent and so many delinquent children are maladjusted In a school where the staff is alive to the problems of the maladjusted, a child may be recognised as such at an early stage, and sent to a special school under the educational authorities Elsewhere a child of much the same type will be left to carry on until he finds himself in a juvenile court when he will be dealt with by the Home Office machinery, being either put on probation or sent to an approved school One cannot hope to get the most suitable treatment for the individual when it is so often a matter of chance which of two entirely different systems the child comes under

If we had welfare organisations on the Continental lines instead of criminal courts for children of school age, any child needing special treatment could be dealt with according to his needs Results would not be influenced by a rigid and artificial distinction

LEGAL RESPONSIBILITY IN BLOOD-TRANSFUSION

SIR,—May I have the opportunity, perhaps, of allaying the fears expressed by Dr Leyton in his letter last week

I think I am correct in saying that the allergic manifestations of migraine are rather unlike those of the allergic conditions mentioned in my paper, in that it can only very rarely, if ever, be treated on allergic grounds, and secondly, if there is a sensitivity basis present, skin tests are never positive—i e , indicating that there are no circulating non-precipitating antibodies that can be demonstrated

Furthermore, recent work[1] shows that, genetically, there does not seem to be any evidence that migraine can be included among those allergic conditions which are considered unsuitable in a donor The possibility, however, of mendelian characteristics being transmitted by transfusion, an idea regretfully abandoned in the 17th century, reopens a vista of limitless extent

Where cases of the passive transfer of sensitivity from donor to recipient have occurred, the sensitisation is not of long duration, and, in fact, the chief problem in transfusion work is to avoid producing reactions in donors who have "reagins" in their plasma

Finally, I should be most grateful to Dr Leyton if he could produce any evidence, published or personal, that migraine is transmitted by transfusion

North London Blood Transfusion Centre,
Deansbrook Road

CIRCUMCISION

SIR,—May I add a few remarks to those of "Sir Daniel Whiddon"? First of all some historical notes

According to the Bible, circumcision symbolised God's covenant with the people of Abraham—i e , all those belonging to the House of Abraham, including those of non Jewish origin (And ye shall circumcise the flesh of your foreskin and he that is eight days old shall be circumcised among you, every man child in your generations, he that is borne in the house, or bought with money of any stranger, which is not thy seed') This latter circumstance supports the hypothesis that circumcision was only a form of tribal marking, enabling the nomadic Jews to produce a secret sign of the fact of belonging to one tribe All other explanations of the purposive character of circumcision are of modern origin

At the time of the ancient Jews, circumcision was not practised by the Semitic tribes who surrounded them This transpires from the Bible in connection with the amorous adventure of Shehem, who wished to marry Dinah, Jacob's daughter, and was given permission on condition that every male of you be circumcised.

Apart from Jews, only Mohammedans practise circum (The term Mohammedan is not synonymous with Arab the Koran we find no references to circumcision on Hadish, the explanatory text of the Koran, mentions According to the latter Mohammed declared *hoft* (cir cision) to be compulsory on all his followers. Why the made compulsory ? No one knows with any degree of cert Educated Mohammedans, like Jews, mention hygienic re However, it is more likely that Mohammed, who that he and his people were the descendants of Ishmael was one of the sons of Abraham and the Egyptian H intended to establish a closer relationship between h his people, and Abraham himself by affirming the circumcision Abraham, by the way, is one of the imposing figures in the Koran Even the great festiv Beyramm commemorates the sacrifice of Isaac.

Modern Mohammedans and modern Jews try to a modern justification for the practice of circumc But the prepuce is no hindrance to personal hygie a person wishes to wash properly , its removal ha increased resistance to venereal diseases , and cision does not reduce sexual desire

The statements of Sir Daniel Whiddon should ever, be amended in one or two particulars First, human prepuce is not only a protective covering for glans penis, but, by the secretion of its glands (sme it gives the glans a greasy surface which facilitate entry into the vagina Secondly, Sir Daniel says the prepuce unfolds as the penis advances through vagina , but actually a normal prepuce is unfolded, and the glans is uncovered, at the tim erection Thirdly, in asking "Is there such a th a baby with phimosis ?" he replies "I have neve one" But phimosis is not uncommon among ba though rarely sufficient to obstruct urination, male babies have to be examined after birth to see they have phimosis or the condition termed cellularis preputii ad glandem which can be relieved after birth, but not so easily later On the other phimosis, when it is present, can be relieved eas plastic surgery even without recourse to circumc and the advantage of such operations is that the survives to perform its physiological function Sir Daniel's opinion that circumcision is a practice, to be avoided wherever possible

Obituary

CHARLES BERNARD GOULDEN

O.B.E., M.A., M.D., M.Chir. Camb., F.R.C.S.

r Goulden consulting ophthalmic surgeon to the don Hospital, consulting surgeon to the Royal don Ophthalmic (Moorfields) Hospital, and formerly sulting oculist to the Household of Queen Mary l at his home at Shepreth on Sept 20, at the age 4

e was the eldest son of the late H J Goulden of terbury, and he was educated at St. Edmund's lege and at Downing College Cambridge Later always spoke gratefully of his years at Downing till then, he said he had had no outside interests opt music At Cambridge his horizon enlarged, but still worked hard for his parents were not wealthy he knew that he had his own way to make He pleted his medical education at the Middlesex spital, where he held a Freeman scholarship and a pold Hudson exhibition He took his M.B. in 1904 his F.R.C.S. a few months later After holding a se-appointment at the Middlesex he went to Moor ds, and one of his senior colleagues recalled him as e of the best house-surgeons we ever had' But could not afford the unrewarding first years of con ant practice in London, and after a period as onstrator in anatomy at the University of Bristol finally settled at Oldham where he was appointed to staff of the Royal Infirmary

n 1916 he left Oldham to serve in France where he ame Sir William Lister's right-hand man at Boulogne er he was put in charge of an ophthalmic centre at nen. For his work there he was mentioned in des ches and appointed O.B.E. in 1919 On demobilisation was offered an appointment at the London Hospital his Metropolitan colleagues welcomed his return n afterwards he joined the staff of the Victoria spital for Children in Tite Street and the Queen xandra Hospital Millbank He was also appointed the staff at Moorfields, where he soon became dean the medical school At the London Hospital he also ed in the work of teaching and became lecturer in thalmology at the medical college In due course also examined for the M.S. Lond the F.R.C.S. and D.O.M.S., and later he served on the board of advanced dies of the University of London and on the com tee of applied optics of the Imperial College of Science a teacher he showed the same qualities which served so well as a surgeon—precision of thought decision appropriate action meticulous attention to detail where necessary ruthless determination In 1924 published his Moorfields lectures for the D.O.M.S. rse, under the title of *Refraction of the Eye* and it characteristic of Goulden that he succeeded in king the section on optics no less lucid and interesting n the more clinical parts. In 1924 and again in 3 he was chosen to give the Montgomery lectures the Royal College of Surgeons in Ireland.

When the second world war began in 1939 he found ple scope for his energies first of all in the day-to- clinical work at The London and Moorfields and n as adviser to the Ministry of Health on the ophthal side of the Emergency Medical Service. His owledge of the men available and his understanding the needs of the different areas made his service aluable The strain however was severe, since this rk entailed much travelling in London and the Home nties. He lived partly in London and partly at preth and he experienced the difficult times of aerial nbardment. He also undertook the supervision of much of the actual work in the F.M.S. hospital at odmayes, and for a man of any age this volume of rk was most exacting

With the close of the war he retired from his appoint- nts at the London Hospital and at Moorfields. He l in fact left the latter rather earlier but had returned fill the place of younger men serving with the Forces. t though Goulden retired from hospital he continued private practice and in the years 1944–46 he was president of the Ophthalmological Society of the United Kingdom He filled this office with great distinction and his presidential address on Purkinje was an indication of his great interest in history Most of his address dealt with Purkinje's *Commentary on the Physiological Examination of the Organ of Sight and Cutaneous System* Goulden said this book was written in ecclesiastical Latin difficult to translate, and one suspects that he studied it in the original

M. H. W. recalls how just before the late war Goulden bought a delightful little house at Shepreth near Cambridge and as time went on he spent more of his time there and less in London. It was a sad blow to his friends when they heard that he had undergone a severe operation, but those *who visited him afterwards in the London Hospital* were filled with admiration at the physical and moral courage which he showed. This misfortune hastened his retirement from active work, and he now lived entirely at Shepreth where he enjoyed the beautiful surroundings and the opportunity of frequent visits to Cambridge to his old college Downing and to the dinners of the Cambridge Medical Graduates Club He continued to come to London also till very recently but when I called on him early this year could not fail to see how frail he had become though still retaining all the keen intelligent interest in affairs which he had always shown.

All of his friends must feel deeply the passing of one whose influence on the ophthalmological world especially on the side of education, has been so considerable and whose charming and often amusing companionship was always so acceptable

In 1911 Mr Goulden married Miss Norah O'Brien There were no children of the marriage

JOHN FRANCIS CARTER BRAINE

M.D. Durh., F.R.C.S., F.F.R., D.P.H.

Mr Carter Braine, director of the radiotherapeutic department of Guy's Hospital and civil consultant in radiotherapy to the Royal Navy, died at his home in Speldhurst on Sept 20

He qualified from Guy's Hospital in 1910 and at once joined the R.A.M.C. to serve in France and later in East Africa. On his return to Guy's at the end of the war he was appointed demonstrator of anatomy and in 1922 he took the F.R.C.S. a distinction also held by his father and grandfather For some years he worked in the department of pathology under Prof Adrian Stokes, and while Griffiths demonstrator he submitted the thesis for the M.D. of Durham University for which he was awarded the gold medal He held the post of chief assistant in the old actinotherapy department at Guy's before he was appointed to the staff as surgeon to the radiotherapy department in 1935 He was also a member of the staffs of the West London Hospital and *the King Edward VII Hospital Windsor*

During the late war Carter Braine acted as adviser in radiotherapy to the group officer and his help was of inestimable value in the organisation of radiology in the Guy's sector When the war broke out all the radiotherapy beds at Guy's were closed and the equipment was moved from London. One unit was taken to Sherwood *Park, Tunbridge Wells, and there by arrangement with* the medical school he was able to continue his clinical work When the Guy's U.S.A. Hospital was opened at the Wilderness near Sevenoaks, in 1941, it proved possible with his help to create, in hutted accommodation a radiotherapy department which remained in use until the end of the war when it was transferred to Pembury Hospital. During the whole period Carter Braine never spared himself and he must have covered well over 100 000 miles travelling between Tunbridge Wells, Pembury the Wilderness and London driving himself in all weathers and in the blackout

He was a foundation member of the Society of Radiotherapists of Great Britain and Ireland and he was a member of the official British delegation to the fifth International Congress of Radiology in Chicago in 1937 He also acted as assistant treasurer and member of the board of management of the sixth International Congress of Radiology in London in 1950

Three of his colleagues have sent us this joint tribute

"The first deep X ray plant in England was installed at Guy's, and from these early days Carter Braine worked unceasingly to improve techniques and results Few could claim the wealth of experience which he possessed His clinical judgment, tempered by a profound understanding of the suffering and anxiety of his patients, was an inspiration and challenge to all who worked with him His constant enthusiasm and encouragement evoked a loyalty in his staff which can seldom have been matched To his great generosity many can testify, and he unhesitatingly used his own equipment to treat hospital patients if he felt it was to their advantage Not least among his many talents was an ability for organisation, which reached its zenith during the war years

"Though his professional life was extremely busy he had wide interests outside his work He dearly loved the country and this was reflected in the careful husbandry of his farm He was interested in art and architecture, as well as all things mechanical, and he delighted in visiting factories and research departments to see for himself how things were made He was a keen and competent photographer, an interest reflected in the excellent clinical photographs and lecture slides of his department

"Despite his vast experience, he was the most modest and unpretentious of men His capacity for work was prodigious and, being physically very robust, his endurance was astonishing He had a great sense of humour and a temperament that was singularly equable He delighted to entertain, and his remarkable memory served him well in argument and discussion To his patients he was indeed the beloved physician, whose sympathy and understanding never failed"

Mr Carter Braine is survived by his wife and one daughter

SANTO WAYBURN JEGER
M.R C.S , M P

Dr Jeger, who has for the last eight years been one of the medical Members of Parliament, died on Sept 24 at the age of 55

He spent his early life in Cardiff, where he was educated at elementary and secondary schools and at the University College of South Wales Having completed his medical training at the London Hospital in 1923, he settled in general practice in Shoreditch, where he soon proved himself an able and popular doctor The strain of continued overwork in this heavily bombed district during the late war, and his responsibilities in charge of a mobile ambulance unit, contributed to the coronary thrombosis from which he never completely recovered

[Elliott & Fry

His political career also started in Shoreditch, for he was elected to the borough council in 1925, became mayor in 1930, and in the following year began his 15-year membership of the London County Council About this time he took an important part in the early activities of the Socialist Medical Association, and during the Spanish civil war he twice went to Spain on behalf of the Spanish Medical Aid Committee

In 1945, he was elected Labour Member of Parliament for South-East St Pancras, and after the redistribution of parliamentary constituencies he sat for Holborn and St. Pancras South In 1946 he visited Austria as a member of a Parliamentary delegation

B S , one of his medical colleagues in the House of Commons, writes

"Jeger served his constituents in Parliament as only a practising doctor can He brought into the House an atmosphere of realism tempered by his ideals and based upon his [illegible] contacts with the needy and the sick His special interests lay in the pursuit of remedies for the soci physical ailments of humanity For this reason he ardent supporter of the National Health Service, and speeches in support of the principles of a free and hensive service were models of close reasoning and right to a degree He was bitterly opposed to the im of any charge for any part of the service, and never to make his opposition clear His work as a doctor him to agitate for improved standards of housing that the slum house was his personal enemy, for in every he did we sensed in him his rôle of the physician

"All of us valued his friendship and his mature He had great experience as an administrator before he Parliament and this, combined with his idealism, opinions added weight He loved peace and cruelty The views he held on foreign affairs were a ago thought to be to the Left of some of his colleagues, are now such as almost everyone accepts

"Many of us have cause to remember him with grat for even in the House he was always helpful to those fell sick and needed his help That he worked too and was indifferent to his own suffering, does not any doctor For the pain and distress of others he too sensitive

"I will miss mostly his exquisit sense of humo well burnished weapon which he could use against as easily as against an opponent He could have lived had he so wished, but he preferred to live his life in full"

His wife, who is a journalist, is a member of the L and of Holborn Borough Council, and his brother is M P for Goole

KENNETH EDWARD ECKENSTEIN
M B Lond.

Dr Eckenstein, consulting physician and patholo the French Hospital in London and a former pres the Chelsea Clinical Society, died on Aug 23

He was born in 1881 in Liverpool, where his Wilhelm Eckenstein held the appointment of S consul, and he was educated at Uppingham He qua from St Thomas's Hospital in 1906, taking his M.B. L the following year After holding resident app at St Thomas's, at The Hospital for Sick Chi Great Ormond Street, at the Chelsea Hospital for Wo and at the French Hospital in London he became assistant to Professor Sabrazès at the clinical of Bordeaux, and with his chief he described a method of diagnosing syphilis by complement-fix In 1910 he returned to London to take up the ment of pathologist to the National Hospital for Di of the Heart His years of practice in London interrupted only by his service during the 1914-1 as a medical officer with the French army, for whi later received the Croix de Guerre and was appo chevalier of the Order of the Crown of Belgium and officer of the Legion of Honour

Though he was himself British-born, Dr Ecken spoke French perfectly and he had many contacts the French-speaking communities of London. Bes his appointment at the French Hospital he was physician to the French Consulate, medical insp London French Catholic Schools, consul of Mona London, and a correspondent of the *Swiss Observer*

For over forty years he was closely associated with Chelsea Clinical Society, which he served as secr president, and treasurer, holding this last office till end of his life He rarely missed a meeting and his and lively conversation added greatly to the int the dinners which traditionally precede these me He leaves a widow and one daughter

NEST KAHAN
M B Lond., D P M., D C.H.

Mrs Kahan, registrar at the Horton Hospital, Ep died on Sept 16 at the age of 42 Her maiden name Thomas, and she qualified from the Royal Free Hosp in 1934, taking her M B Lond three years later most of the late war she held an appointment as phys at the E M S Southern Hospital, Dartford, Kent W she gave up that appointment in 1947 her interest to psychiatry, but in 1948 her career was for the time interrupted by ill health She was appointed n Hospital in 1940 and for the greater part of her l of service there she held the position of registrar btained the D.P.M in 1952.

H W writes: 'Dr Kahan was a shrewd and l clinician and her experience and special qualifi s were invaluable during the difficult period when n Hospital was reverting to its original psychiatric ion She will be long remembered for her happy onship with both staff and patients and for her ne attitude to their problems During the last two she was often in pain and her steadfastness go, and devotion to duty were the admiration of all shared her secret"

r husband is Dr Alexander Kahan, consultant cian to St James Hospital, Balham, and she s a son and a daughter

Notes and News

INQUIRY INTO HEALTH VISITING

THE Ministers of Health and Education and the Secretary of State for Scotland have appointed a working party to advise on the proper field of work and the recruitment and training of health visitors in the National Health Service and School Health Service The chairman of the working party will be Sir Wilson Jameson F.R.C.P and its members are Dr A. Beauchamp (Birmingham) Alderman Mrs K. Chambers, O.B.E., LL.D J P (Bradford) Miss E G Himsworth R.G.N., S C.M (nursing supervisor for Midlothian and Peebles), Miss E. Stephenson, S.R.N S C.M. (chief nursing officer Newcastle upon Tyne) and Dr J F Warin (medical officer of health, Oxford) The working party will be advised by a steering committee also under the chairmanship of Sir Wilson Jameson on which the Government Departments concerned will be represented. This will have the expert advice on social workers and their training of Miss Eileen Younghusband, M.B.E., J.P., and Prof R. M Titmuss

The inquiry work on which will start this month, is expected to deal with the general position of the health visitor in the light of experience now gained—including for example, ways in which she might coöperate with the family doctor and the hospitals—but not with services with which the appointing Ministers are not directly concerned The joint secretaries to the inquiry are Mr R Pronger and Miss M H. Cook, S.R.N (Ministry of Health Chesham House, Regent Street London W 1)

TREASURES OF ORTHOPÆDICS

BEFORE concluding his term of office as president of the British Orthopædic Association, Sir REGINALD WATSON JONES with Lady Watson-Jones, gave a dinner at the Royal College of Surgeons on Sept. 25 when the guests included former presidents of the association and members of the executive. One of his aims as president he said had been to strengthen the younger generation s appreciation of what had been done by their forerunners and he had been disturbed at the thought of many of the historic treasures of orthopædics up and down the country being irretrievably lost With the help of Mrs. Hilda Watson and Lady Probyn-Jones (daughter and daughter in law of Sir Robert Jones) and others, he had in the past twelve months formed the nucleus of a national collection which would be housed for the association, at the Royal College of Surgeons. Local collections—at Liverpool and Oxford for example—should be maintained and extended; and to correlate all these possessions a new office had been created—that of keeper of the archives of the British Orthopædic Association (Robyn Jones doesn t know it yet but he is the keeper of the archives ")

Prof BRYAN MCFARLAND president-elect who presented a chisel used by Robert Jones at his last public operation said that such things were symbols evoking memories. From tradition springs the desire to emulate and if possible surpass the achievement of our predecessors, to maintain their high principles and to hold the ground they gained. Hillary and Tensing had climbed Everest on the shoulders of their fellows, and these on the shoulders of previous expeditions. Such reflections inspired collective pride but personal humility —a firm basis from which to hand on the treasures of the past

Sir THOMAS FAIRBANK recalled a day at Liverpool some 27 years ago when he assisted Robert Jones in conducting the second examination for the M.CH. ORTH and two of the four candidates were R Watson Jones and B L McFarland. He proposed the toast of Two Historic Treasures Happily Still with Us—the president and president elect Mr WILLIAM GISSANE, as a Birmingham surgeon spoke on behalf of what he called the dominions and colonies of orthopædics

The chief guest, Lady Probyn-Jones presented an embroidered smoking-cap belonging to Hugh Owen Thomas and Mrs. Watson had sent a portrait of her father by Copnall. Other exhibits included the signet ring and piccolo of H O Thomas his annotated interleaved copy of the 1st edition of a volume of contributions to medicine and surgery and the annotated letters (some in Welsh) of his great grandfather Evan Thomas which (said the President) give a vivid idea of the atmosphere of orthopædic surgery at that period. Among MSS. were letters on the foundation of the British Orthopædic Association, and among drawings some early etchings by Sir Thomas Fairbank.

From the College of Surgeons library and museum. Mr W R. Le Fanu and Mr W E Thompson showed books, specimens and instruments. The specimens included a series by Sir William Macewen illustrating the growth of bone and another on the transplantation of bone illustrating the essay with which E. W Hey-Groves won the Jacksonian prize in 1916

DANGER FROM THE FIRE

WINTER brings danger of death by burning, especially to children and old people Dr Leonard Colebrook, F R S, writes to remind us that the peak period for serious accidents is from November to April Since Oct 1 it has been an offence for any person to sell or hire an electric or gas-fire, or an oil burning space heater, which is not fitted with a guard conforming to prescribed safety regulations, but the Act does not apply to fires already installed in people's houses, and as Dr Colebrook points out, there are about 4½ million of these now in use, and about 12 million open solid fuel fires Many—perhaps most—of these are not fitted with an adequate dress guard A similar reminder from the London County Council says that every effort is being made—by posters, pamphlets, and working models, and through the teaching of health visitors—to warn mothers of young children of the risks they run by not providing guards There are many new designs of guards at reasonable cost, and these are stocked by the large stores

The London County Council, in a warning to citizens
bout the new law, points out that its public control com
ittee now has the unenviable duty of deciding whether
not to prosecute parents or others in charge of children
der 12 who have suffered serious or fatal accidents from any
pe of unguarded fire—not merely from coal fires, as used
be the case

'he commonest materials associated with burning accidents are cotton and artificial silk, both because they are ignited by short contact with a moderate heat, and because they propagate flames rapidly They are the materials most commonly worn by women and children, and at present there is no completely satisfactory way of making them permanently non flammable Dr Colebrook hopes, however, that before very long it will be possible to make them *much less* flammable, so that if they catch fire they will not cause any extensive burn They would inevitably be a little more costly Up to the present there has been little demand for them, so manufacturers have been reluctant to put them on the market Housewives should be encouraged to ask for them in order to hasten the supply

FRENCH WORK ON THE HEART AND BLOOD-VESSELS

WITH so much to read and so little time for reading, clinicians and laboratory workers alike must pick and choose among the myriad articles poured out yearly by the scientific world, and what more natural than to choose first among those in their native tongues? It is only too easy to overlook or ignore work done in countries with other languages, and this is the cause of much unnecessary duplication of research The Cultural Division of the French Embassy in the United States is doing something towards overcoming this difficulty by publishing in English bibliographical digests of French medical and scientific articles The first of these digests[1] was published last December, for circulation in the U S A, and is available from the office of the Cultural Division of the Embassy[2] It summarises over 500 articles on the heart and blood vessels which appeared during 1945–51 Prof René Leriche contributes a valuable review of cardiovascular surgery in France today In a foreword Prof André Cournand professor of medicine in Columbia University who—like Professor Leriche—is a member of the advisory board for the series, expresses his hope that the booklet will encourage American surgeons to familiarise themselves with current French work Here we find it a little easier to keep in touch with our colleagues over the way, but the English are notoriously weak on languages and these useful summaries will be as welcome here as they are in America

University of St Andrews

Sir Russell Brain, P R C P, is to deliver the inaugural post graduate lecture of the next session of the medical school Dundee, on Thursday, Oct 8 He is to speak on Consciousness and Unconsciousness

Royal College of Obstetricians and Gynæcologists

Leverhulme research scholarships for 1954 have been awarded to Ian Donald Joseph Gardiner, and Matthew Lindsay Paterson The Blair Bell lectureships for 1954 have been awarded to Thomas Everard Christopher Barns and Ian Donald

Charing Cross Hospital

Admiral Sir Philip Vian will deliver the inaugural
of the medical school at 3 P M on Friday, Oct 9, a
Royal College of Physicians, Pall Mall East, S W 1

Wessex Rahere Club

A dinner of this club will be held at the Lansdown C
Hotel, Bath, on Saturday, Oct 24 Membership of th
is open to all Barts men practising in the West (
Further details may be had from Mr A. Daunt B
the hon secretary, 11, The Circus, Bath

American Society for the Study of Sterility

This society is offering an award of $1000 for an ess
infertility and sterility The closing date is March 1,
Further details may be had from Dr Herbert H. T
secretary of the society, 920, South 19th Street, B
Alabama

Professional Nurses and Midwives Conference

This annual conference, which is held under the a
of the *Nursing Mirror*, will take place at Seymou
London, W 1, from Oct 12 to 16 under the preside
Sir William Gilliatt Medical speakers will includ
Arnold Walker, Mr R C Brook, Mr A B Wallace,
Geoffrey Marshall, Dr E B Strauss, Mr Kenneth B
Prof A M Claye, Dr Kenneth Maclean, and Prof C H C

International Orthopædic Congress

The sixth Congress of the International Society of
pædic Surgery and Traumatology will be held at Berne
Aug 30 to Sept 3, 1954 Subjects chosen for discussion in
Treatment of Scoliosis, Orthopædic and Traum-
Problems in Gerontology, Physiological Backgr
Maximal Performances in Sport, Arthrosis of the Hip
articulatory Tuberculosis, Physiology and Pathol
Locomotion, and Surgery of the Hand Further par
may be had from the secretary general of the
M Jean Delchef, 34, rue Montoyer, Brussels, Belgium

Seminar on the United Nations Children's Fund

The World Federation of United Nations Associat
holding a seminar in Paris from Oct 19 to 25 on the w
UNICEF Dr Charles A. Egger, director of the regional
of UNICEF, will give the opening address The
open to doctors, nurses, medical students, auxiliary m
personnel, social welfare workers, and others interes
child welfare Further information may be had fro
World Federation of United Nations Associations, 19,
Kléber, Paris XVI

Royal Victoria Hospital, Belfast

This hospital held a jubilee week from Sept 20 to
celebrate its years of service On Sept 24, at the ceremo
naming one of the wards in appreciation of the services
honorary medical staff (1792–1948), Viscountess Brookeb
unveiled a tablet honouring those who "served the p
of Ulster by day and by night giving ungrudgingly
knowledge and their skill for no fee and reward apart
privilege of helping others"

During the week Lady Wakehurst opened the Herber
department of neurosurgery and neurology, the first s
neurological unit in the province Mr C A Calvert has
appointed director of neurosurgery and Dr R S A
director of the department of neurology The departm
two floored pavilion, includes an operating and dia
centre a 54 bedded unit, and 26 extra beds for the de
logical department It has cost £70,000 and has been
out of free funds

CORRIGENDUM *The Work of a Regional Hospital*—
article by Dr F Avery Jones (Sept 12, p 556) W
General Hospital was stated to have 110 beds. *In fa*
hospital has 127 beds, and it has recently taken
annexe with 35 beds for chronic sick.

Sir Rudolph Peters F R S has been awarded the degree
by the University of Cincinnati.

Prof Joseph Trueta has been appointed a chevalier of the L
of Honour in recognition of his treatment of French wound
Britain during the late war

Sir Andrew Davidson chief medical officer of the D
Health for Scotland in response to invitations from the S
General of the United States Public Health Service the
minister of health of Canada and the American Public
Association, is to visit the U.S.A. and Canada during N
and the early part of December

ERNUTRITION AND UNDERNUTRITION

II EFFECTS *

R. A. McCance
C B E., M A , M D., Ph.D Camb , F R C P F R.S
FESSOR OF EXPERIMENTAL MEDICINE IN THE UNIVERSITY OF CAMBRIDGE

m the Medical Research Council Department of Experimental Medicine, Cambridge

Clinical and General

THE first quantitative way of studying the effects of ernutrition and undernutrition was to follow the ight of the body and it has remained the standard one ere is a wide range of normality in the body weight, wever and it is impossible at present to say where the al weight for height begins and ends. Studies of the nposition of the body (see later) have shown that it l not be the same for all individuals and that it should bably vary with activity age, and sex In a popula n which is enjoying economic prosperity more people overweight than underweight This is due to the position of fat in the subcutaneous tissues omentum nd the kidneys, and to some extent round the heart the distribution again varies with age and sex dwards 1950) In man the lean parts of the body do t account for much of the 'middle-aged spread,' but heart hypertrophies if the blood pressure rises, as it ds to do in obese people and hypertrophy of the liver d alimentary organs has been described in rats which eating enormous quantities of food. The ovaries of se animals decrease in weight (Brobeck et al. 1942– a) There is an enlargement of the kidneys and supra nals (Kennedy 1951)

The loss of weight which follows undernutrition has en investigated on man and animals. It was established Chossat (1843a and b) and has been confirmed many nes since, that the loss of weight—like the gain of ight which has just been described—is a composite ocess (Morgulis 1923) It may consist only in a loss of (see later) but in starvation and also in general under trition the weights of the organs fall—not all however the same extent. The brain bones, and kidneys lose ry little if any weight, whereas the muscles lose a great al, and so do the heart and the alimentary organs wards the close of the last century the loss of weight of e liver pancreas, and similar organs was shown histo gically to be due largely if not entirely to a decrease the size of the cell (Loukianow 1897 1898 1899) M. Harrison has now made these findings more antitative by chemical methods and fig 1 shows some the results which she obtained when she was working th us (Harrison 1953a and b)

The clinical effects of prolonged overnutrition are too ll known to most doctors to require any description re. Some of them however will be mentioned later this lecture. They vary from flat-foot and arthritis to ofuse sweating on the slightest exertion.

The results of severe and lasting undernutrition are ry distressing and have probably not been seen in this untry by anyone practising medicine today Very dernourished people have a characteristic walk and sture With knees slightly bent the trunk and arms ouch forward and the head droops towards the chest lelweg Larsen et al. 1952) The internal body tem rature remains very near the normal but the distribu on of blood between the skin and the internal organs anges quite early in the process of emaciation (Howarth 51) and undernourished people always feel cold. This adds to their misery and they wrap themselves up in any clothes or blankets they can obtain They lose the ability to hold urine in the bladder without an urgent desire to pass it, and also tend to make very large amounts of urine particularly on lying down The two together prevent them getting any restful sleep and towards the end they begin to form thin watery stools and are unable to control their passage It is probable that this diarrhœa is accentuated by atrophy of the glands lining the bowel wall, coupled with the nature of the food which these people are generally forced to eat. There is no evidence that it is due to any specific infection The diarrhœa and polyuria are perhaps the most demoralising aspects of the terminal stages of famine The undernutrition in Germany in 1946–47 was never bad enough to provide clinical cases of diarrhœa but polyuria was usual This was partly due to the large amounts of soup which were consumed morning, noon, and night but the polyuria should be regarded as part of the redistribution and accumulation of extracellular fluid which begins quite early in the syndrome and may appear clinically as œdema (McCance 1951) Undernourished people, particularly if they are exposed to the weather tend to get a dry scaly skin and sometimes hyperkeratosis (Keys, Brozek et al. 1950 McCance and Barrett 1951) In most people the blood pressure falls; the level of serum proteins tends to do the same and there is usually a mild degree of anæmia Some of the more puzzling effects of undernutrition are the enlargements of the parotids and of the male breasts (McCance et al 1951 Helweg Larsen et al. 1952)

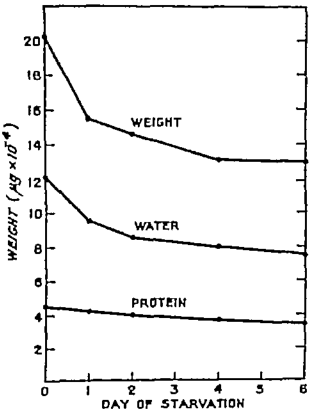

Fig 1—Effect of starvation on weight of liver cell of male rats and on weight of water and protein in it.

The Composition of the Body

The body may be regarded as being made up of the 'lean' portions and the fat Once the latter has been deposited, it may be considered as lying to some extent outside the active metabolic framework of the body The 'lean' can be further subdivided into the cell mass and the extracellular system and is very constant in composition during health. Until comparatively recent times chemical analysis of a body after death was the only way of getting at its composition and this method still remains the only one for certain purposes, and the most accurate one for most. In the 1930s however methods became available for estimating the volume of the extracellular parts of the body in living animals and in man. Knowledge thereupon increased and when it became possible to measure the total amount of water in the living body the physiologists were able to get some idea of the volume of the cell water by 'difference' The fat in the living animal and man was next assayed successfully by two independent methods One of these

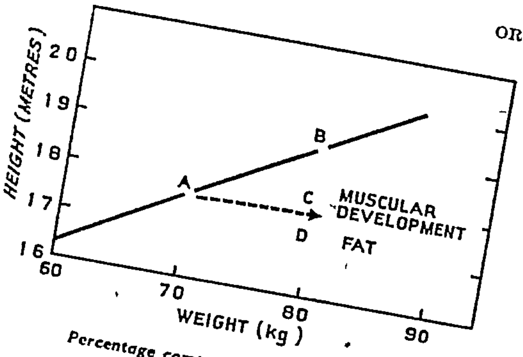
The second Humphry Davy Rolleston lecture for 1953 delivered before the Royal College of Physicians on May 7 Lecture I appeared in last week's issue.



Percentage composition of the body

	A	B	C	D
Cell mass	56 0	56·0	58 2	49·0
Extracellular fluid	21 0	21 0	21 7	18 4
Fat	16·0	16 0	14 0	26 5
Minerals	7 0	7 0	6 1	6 1

Fig 2—Effect of a gain in weight on the composition of the body

(Behnke 1942, 1945) depended upon the principle that fat and lean have different specific gravities By finding out the specific gravity of the body the percentage of fat in it could be calculated on the assumption that the lean part had a known and constant value The other depended upon finding out the total water in the body and hence the weight of "lean" in it The fat was derived from the difference between this and the weight of the body (Osserman et al 1950) A refinement of this method was worked out independently by McCance and Widdowson (1951) by which the weight of the cell mass was calculated from the cell water, and the weight of the extracellular system from its volume The fat was again derived from the difference between the sum of these figures together with the bony materials, and the body-weight The advantage of this method was that it could be applied to people with abnormal "leans"— with œdema for instance

TABLE I—PERCENTAGE OF FAT IN NORMAL MEN AND WOMEN

Men			Women		
Height (m)	Weight (kg)	% fat	Height (m)	Weight (kg)	% fat
1 65	62 8	18 1	1 60	63 0	16 0
1 67	56 8	17 9	1 62	63 2	19 8
1 74	81 2	22 4	1 64	74 0	28 5
1 80	62 1	10 3	1 64	75 5	21 5
1 80	72 2	15 2	1 68	55 2	12 0
1 81	56 3	7 2	1 75	79 2	21 1

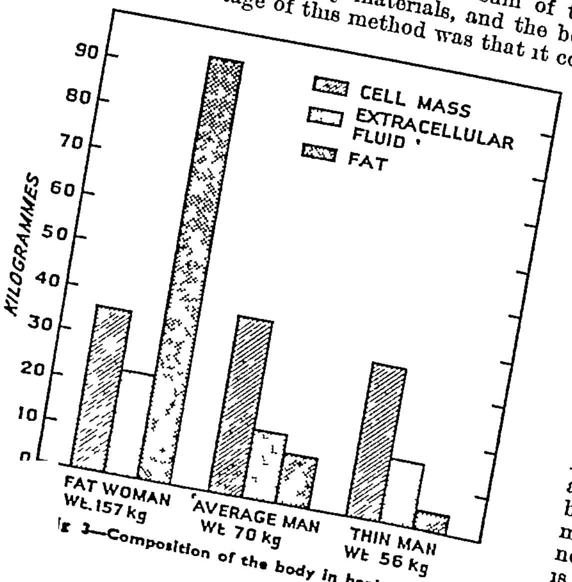


Fig 3—Composition of the body in health

Fig 2 shows the line relating normal weight and and the composition of the body of four ima young men, A, B, C, and D C differed from A muscular development, D only in the amount of his body Notice how three people of the same w can vary in composition, and that a light man may have exactly the same composition as a he man (B) if he is not so tall Table I shows the in the percentage of fat found by McCance and Widdo (1951) in a group of men and women, all of whom reg themselves as normal and were accepted as such for investigation The variations are large and shoul studied The lean parts of all these people were more constant in composition and always cont 70–72% of water

As people get older their weight tends to This is due to laying down fat, but another change takes place at the same time which masks the amounts actually being deposited This is the of cell mass due to reduced activity which gener accompanies advancing age (Brozek 1952) Welham Behnke (1942) have made a series of individual of the bodies of athletic young men, and compared with those of groups of naval men who were not athl When the sailors and the athletes were the same the former were found to contain much more fat and correspondingly less muscle (see fig 2) Brozek (1952) has made a study of active and sedentary middle-aged men and obtained a similar result

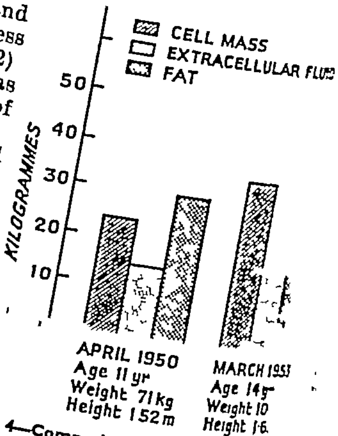

Fig 4—Composition of the body of a

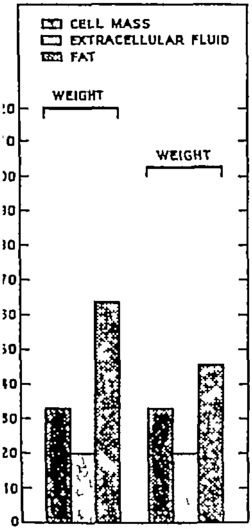
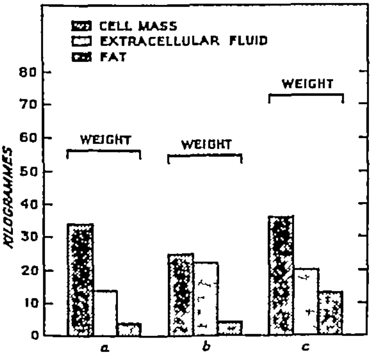
Fig 3 shows the composition of the body of a very fat woman and of that old friend the 70-kg man whom we have all known from our student days I have taken the liberty of adding myself as an example of a thin person The mous amounts of fat being carried about by Gross are a terrible warning to the overindulg Not that they are records by any means Lambert, whose height was 5 ft 11 in, weighed 73 when he died (aged 39) in 1809 (Gould and Pyle Encyclopædia Britannica 1910–11), I expect that 530 lb, or 240 kg, of this was fat Coe (1751–52) a grocer of height 5 ft 9 in who died at the age weighing 616 lb—probably 425 lb, or 192 kg, of it fat Women have been recorded up to 850 lb 1878, Correspondant, France 1890), which make Gross seem light, but even her burden weighed than the 70 kg man did, and still more than I do furthermore, Mrs Gross had no more cell mass th have with which to carry about all this weight wonder her complaint was breathlessness. There another rather interesting thing about her She little too much extracellular fluid in her "lean" (and Mach 1949) This may be regarded as the blood, lymph, and tissue fluids necessary for the nour ment of that great mass of fat Quantitative work no support to the views of those who believe that is due to a retention of water (Oertel 1891, von N 1910, Grafe 1920, Copeman 1950, Greene 1950, burger and Mathé 1952) ig 4 shows the progress of obesity in a boy aged 11 rs when first seen and aged 14 when next investigated added 18 cm to his height in this time and developed his muscular mass to some extent but more than half of his increase in weight was due to fat, and the proportions of his body changed for the worse



5—Composition of a fat woman (a) and e same woman after “ slimming (b)

If an obese person s weight is reduced by a diet containing enough protein to maintain the cell mass the evidence is that the loss of weight is entirely due to a loss of fat The N balance is not negative (Newburgh 1944) Fig 5 shows results which we have ourselves obtained

Fig 6 shows the composition of a very undernourished man He was a German, just back from a Russian labour camp I have again inserted myself for comparison, and 6 also shows the effect of two months ease and plenty the undernourished German He had very little fat his body when he first came back but so have I it is clear that a small amount of fat in the body is proof of undernutrition A rapid fall in the amount etter evidence, but the most characteristic feature real undernutrition is an increase in the amount of racellular fluid in the lean ' and a decrease in the mass This only begins to happen to any extent after siderable loss of weight, unless the protein intake is fficient to meet the body s requirements, when it' st begin to happen from the first



6—Composition of a thin man (a) an undernourished man (b) and the undernourished man after rehabilitation (c)

There is no difficulty about explaining most of these changes The deposition of fat is due to the food entering the system providing more energy than the activities of the body demand. The loss of fat and cell mass in undernutrition are equally simply explained They have been mobilised and metabolised to provide the energy and amino-acids for organs like the kidney, brain and heart which have maintained the essential services of the body The increase in extracellular fluid is probably due to a number of causes. Replacement is certainly one As the fat in the marrow is removed its place is taken by extracellular fluid A vacuum in the bones would be impossible, and extracellular fluid is the only material with which the spaces previously occupied by fat could be filled As undernutrition gets worse the large deposits of fat round the kidney and in other sites become spongy masses of connective tissue and extracellular fluid Similar changes take place in the subcutaneous tissues Another reason for the increase in extracellular fluid in the body is the change in the relationship of surface area to body weight Surface area decreases much less than the body weight and consequently the large amounts of extracellular fluid in the skin come to contribute more and more to the body weight There may be changes in the level of suprarenal activity, and many other suggestions have been made but they must all for the moment be regarded as non proven (McCance 1951)

With so much extracellular fluid in the body and the loss of coherence between the cells, it is curious that all undernourished people do not get great collections of extracellular fluid in the dependent parts Some do and hunger œdema has become one of the proof marks of advanced undernutrition ; but it is surprisingly uncommon People can die of chronic undernutrition without ever having had œdema Animals very rarely get it If it does appear in man its volume is usually only a small fraction of that of the surplus extracellular fluid which the sufferer is carrying, and its appearance should be regarded as an incident rather than a milestone in the march of the disease (Widdowson and McCance 1951),

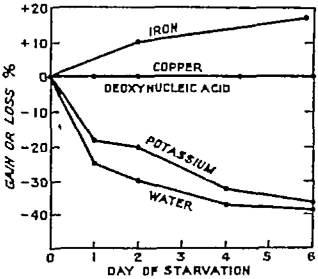


Fig 7—Percentage gains or losses of minerals from liver cell of male rats.

The changes which have been discussed are characteristic of the body as a whole but not necessarily of the organs or of the cells. Starvation for six days did not increase the percentage of extracellular fluid in the liver of rats, nor reduce the percentage of protein, although the weight of the organ fell and of the cells in it (Harrison 1953b) The loss of weight was largely due to the loss of protein and water in the proportions in which they were initially present in the cells (fig 1) but the percentage of fat actually rose in female cells Fig 7 shows other observations that have recently been made The cells lost no desoxynucleic acid or copper—both constituents of the nucleus—and consequently their percentage in the liver as a whole would have gone up The amount of iron in the liver cell may actually increase due to the deposition of iron which has become functionally redundant elsewhere in the body Water and potassium fell in equivalent amounts so that there was no osmotic or

TABLE II—PROTEIN KATABOLISM AND OXYGEN CONSUMPTION DURING STARVATION

—	Infants	Young men	Old men
B M R (cals /kg /24 hr)	50	26	21
Nitrogen katabolised (g /kg /24 hr)	0 075	0 17	0 12
Percentage of calories derived from protein	4	15–20	15–20

ionic disorganisation These findings bring to mind Gamble, Ross, and Tisdall's classical work in 1923, and help us to understand how surprisingly normal an undernourished person or animal may remain If undernutrition produced changes in the composition or in the osmotic pressure of the body fluids, as well as in their volume, its effects would be far more devastating than they are

Fragmentary as these observations are at present, they demonstrate the great risk of premature generalisations about the results of overnutrition and undernutrition Their effects must be expected to vary according to the system upon which attention is being directed Organs may not behave like the body as a whole, and the composition at the start must make a difference to the train of events later on Unlike the liver cells of the healthy adult female rat, for instance, which contain almost no fat, the liver of the newborn guineapig contains 12% of fat, and undernutrition may reduce this in a fortnight to 5% Age also must be expected to alter the effects of overnutrition and undernutrition We have recently been investigating a very striking instance of this (table II) Protein provides about 19% of the basal energy requirements of a healthy starving man, and he breaks down about 0 17% of his body nitrogen per kg of body weight per day This was well known, or at any rate the information necessary to establish the point was obtained many years ago We have recently found, however, that protein provides only about 4% of the basal energy requirements of a normal newborn baby, so that, in spite of his higher basal metabolic rate per kg of body-weight, he breaks down in starvation only 0 075 g of his body nitrogen per kg of body-weight per day (McCance and Strangeways 1954) We have no knowledge at present of how the protein is held in the tissues, but we may think of it tentatively as being due to the action of a growth hormone which continues even during starvation to direct the metabolic turnover of amino acids towards anabolism (Greenbaum 1953)

Growth and Longevity

There are often great differences between the sizes of two littermates One piglet, for example, may be three times the size of another, probably because of differences in the nutrition of the two fœtuses *in utero* The placing of a placenta may make all the difference between success and failure There is probably a limit to the amount of nutrients which a mother can pass to her young *in utero*, for twins are generally smaller than single babies (Blegen 1953), and this is true of animals also (Hammond 1952)

The weights of the infants born in an undernourished community appear to be slightly smaller than those born in the same community if it is in good nutritional shape (Smith 1947a and b, Keys, Brozek et al 1950, Dean 1951) These differences may seem small, but they may be made much larger in animals and can be magnified in man also if the tendency of overnourished and obese women to produce very large babies is taken into account (Jackson 1952) Hammond and his fellow workers (1952) have shown the importance of a high plane of nutrition during the last weeks of pregnancy in domestic animals if strong and fully developed offspring are to be expected at term The young of a mother on a low plane of nutrit re anatomically and physiologically immature, and, although they are the correct calendar age at they resemble the premature offspring of a moth high plane of nutrition In other words und has delayed the whole process of development wi otherwise interfering with it, so that the animal's logical age is younger than its calendar age would one to expect If the gestation period of the mother a low plane of nutrition could be artificially prol by progesterone for instance, the probability is would ultimately deliver themselves of young were some weeks or months older by calendar from conception date than their developmental (i.e., biological) age would suggest

Undernutrition also delays the growth of animals birth and may modify their form for any given calen age The farm animals have been studied more any others (Hammond 1952), but the same fact often been demonstrated in rats, and also that th animals have the capacity to make good this defi their biological development if they are given the ch It has also been shown, however, that protracted nutrition in rats not only greatly delays the rate of but also very materially prolongs the calendar life of animals (McCay et al 1939, McCay 1952) Senility takes them only when they are allowed to eat the and so complete their development and become It seems desirable that more of these experiments be done particularly on other animals which do not tinue like the rat to grow slowly throughout most of lives Only thus will it be possible to find out w the epiphyses in the long bones remain ununited enough to enable all such animals to attain a reason normal size Nutrition may not be the cause of difference (Ministry of Health 1953), but if the he attained by wealthy and slum populations are indication of what might be expected to happen in it would look as though the epiphyses would unite a perpetually undernourished youth could attain the stature to which he was heir The effect of reta growth of animals on their mental development offe wonderful field of investigation to anyone who acquire the necessary facilities

Part of our work in Germany in 1946 was to effects of a change of diet on a group of children who were known to have had a low calorie for some years These children were shorter and than English and American children of the same cale age Their "bone age" was also younger The of diet provided the children with unlimited cal largely in the form of bread It also provided calcium and vitamin D, although there is no evide that the children were in need of the vitamin A year of unlimited calories the children were nearly a and heavy as English and American children of calendar ages and their bone age had also increased nearly two years They were, like the rats, making for lost time, but by raising their rate of developm in this way the children's biological age was by nearly two years within the space of only one the calendar This may have been a nutritional but further reflection leads me to suggest that we have taken six to twelve months off those childr expectation of life by feeding them up in this way "T race is not" necessarily "to the swift nor the battl the strong but time and chance happeneth them all" (*Ecclesiastes*, chap 9, verse 11) We may shortening the lives of the generation now growing up this country by trying to make them grow faster school meals and school milk

Children who are generally overweight have been fo to be taller and to have an older bone age than th calendar age would lead one to expect (Bruch Le Marquand 1951) There is, therefore, some evid that the rate of growth can be forced by overfeed w this comes about is at present a matter of conjecture there are two possibilities Firstly if overnutrition ls initially to hypertrophy of the islets of Langerhans ch insulin may be available and liberated in the body ing the earlier years of a career of overnutrition—and re is evidence that insulin can act as a growth hormone st 1952) Secondly the more food eaten the more va is likely to be produced and swallowed and if inados (1951) is correct in finding that human saliva tains a growth promoting factor for the golden nster it may possibly contain one for man himself l perhaps be one of the factors which helps to keep rition and growth ' in step

)vernutrition and obesity certainly tend to shorten adult's life All are agreed about this life-assurance tistics show it (Newburgh 1944 Evans 1952) animal periments confirm it (McCay et al 1941, Kennedy il Hansson et al 1953) To some extent this mature demise may be attributed to purely mechani causes The rats for example get so fat that y become almost immobile. They are no longer e to clean themselves they drag themselves round ir cages and parts of the skin which are subjected to isual pressure or friction lose their fur and ulcerate e fat man is more likely to break his ankle or his iur if he slips off the kerb and he is always a worse ration risk than the thinner man in the next bed

)vernutrition however interferes with the expectation life in much more fundamental ways than these insson et al. 1953), and some instances of its effects st be considered There has been a controversy many years as *to its influence on the composition* the serum The level of cholesterol therein has n the focus of interest owing to its relation to erial degeneration from which the overnourished particularly liable to suffer (Gardner and Gains ough 1928 Okey and Stewart 1932–33 Steiner l Domanski 1941 Gertler Garn and Lerman 1950 rtler Garn and White 1950, Moses et al 1952) en et al (1952) found that a frugal vegetarian diet ded to give lower values in the serum even in young ilts, than a rich diet containing much meat, cheese l eggs, but the most important contributions to this ject in recent years seem to have been those of Keys l his fellow workers (Keys Mickelsen et al. 1950 ys et al. 1952) Keys (1952) pointed out that some ple and some families have naturally high serum olesterol and that they tend to get arteriosclerosis very ing He also showed that, in man putting up the lesterol intake at any age did not usually raise the um-cholesterol although it had some effect in old ple According to him the serum-cholesterol tends to rease with age, and this is due to the consumption not much of cholesterol as of fat In undernourished nmunities the serum cholesterol may even fall after age of 35 and if the intake of fat is kept very low it y not continue to rise after this age even if the nutri n is adequate We can confirm these findings about um levels in undernutrition from a limited series of n who were investigated in Germany in 1946 (fig 8) erlock and Walshe 1951)

A high blood pressure is one of the results of over ing although there is always some uncertainty about measurement in very fat people The change seems precede arterial degeneration and may perhaps be a se of it. At all events hypertension has been shown be associated with obesity in quite young people (Odell l Mengert 1945) and the fat boy of 14 to whom refer e has already been made has a blood pressure of)/80

)vernutrition certainly predisposes to diabetes. This is true of mice (Mayer et al. 1952) as of men (Evans 12) Are we to assume that this is due to arterial eneration of the vessels supplying the islets? Probably not, because in the mice the islets are hypertrophied when the animals get diabetes and moreover undernutrition in any community decreases the incidence and mortality from diabetes so that the plane of nutrition itself seems to be the important variable. It seems more reasonable to regard the diabetes of overnutrition as a failure of the islet tissue to keep pace with the metabolic demands made upon it A similar reason may underlie the other pathological lesions which have been described in the kidneys and other organs of obese animals (Brobeck et al. 1942–43a, Brobeck 1946 Bleisch et al 1952) In other words these lesions are not just the secondary effects of a rise in the serum-cholesterol and arteriosclerosis but are really specific signs of premature old age and the converse of the prolongation of youth conferred by undernutrition The latter is a much more stimulating thought Underfeeding has been shown to prolong the life of a protozoon, *Tokophrya infusionum* (Rudzinska 1951) Forcing the metabolic pace may well turn out to be an ageing factor in cells in many parts of the body of higher animals, and it is certainly possible that the easiest way to add five years to man's expectation of life would be to prolong his years of growth on the calendar by controlled undernutrition and to maintain him on a low plane of nutrition for the rest of his life The infectious diseases like tuberculosis might cause trouble but if the brave new world of the future is ever enticing enough to make a man wish to pay this price for another five years in it, such things may have ceased to trouble us For the dyet of youth is not convenient for old age nor contrariwise (Cogan 1588)

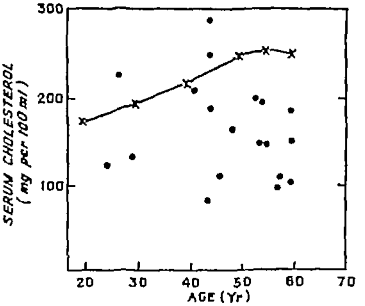

Fig 8—Cholesterol in serum of American citizens and undernourished German men: X——X, average for 1500 men in Minnesota; ● individual undernourished men in Germany in 1946.

Psychological Effects

Restlessness, movement and overactivity seem to be very fundamental aspects of mild undernutrition They are displayed by animals as low in the scale of evolution as hydra which is only 2 cells in thickness and possesses a most primitive nervous system (Buchsbaum 1953) as well as by mammals like rats which when they are underfed behave in rather a characteristic way They are always on the move they leap up on the side of the cage *whenever they are approached* and when they are given food they do not eat it quietly in the normal fashion but carry it about and try to make little piles of it in the corners. These their fellows at once steal and place elsewhere—and so the act goes on Rats deprived of all food behave rather differently in our experience and tend to lie huddled together after a day or two without much movement A considerable amount of work has been done on the increased movement of hungry rats (see Keys, Brozek et al 1950) and much more might profitably be done on the basic effects of overnutrition and undernutrition on animal behaviour So far as man is concerned a good state of nutrition is essential for mental contentment, and the converse would appear also to be true, for psychological trauma can impede growth (Widdowson 1951)

A disinclination for physical exertion often makes fat people appear placid, and they may be—in fact this may be one of the reasons why they are fat But some of the men who have made their mark on history have been distinctly stout—William the Conqueror, for instance, and Sir Winston Churchill When Julius Cæsar wished to have men about him that were fat, he really meant, I think, well nourished men, and fatness was his proof of this

The psychological effects of undernutrition have a literature which goes back to the dawn of history (Keys, Brozek et al 1950, McCance 1951, Helweg Larsen et al 1952) No summary of it can possibly do justice to the force and pathos of the originals Famine in some shape or form has been the lot of prisoners, castaways, explorers, the populations of cities, and even of whole countries, and, although the writers have mostly been sufferers as well, and consequently liable to subjective bias, the accounts they have given leave no doubt about the effects of famine on behaviour

As food gets short, people begin to get very careful about wasting it Later everything that can be eaten is diligently sought, and leaves, grass, and even earth may be taken in the hope of deriving some help from them (McCance 1951) Where hunger and satiety are fellow citizens, the rubbish-bins of the rich are scavenged for everything edible in them by the starving poor As the famine gets worse, food begins to occupy more and more of people's thoughts, other interests lapse and after a time it becomes the only topic of conversation and the cause of ceaseless activity Loyalties change as the organisation of society breaks down At first any food obtained will be shared with the family or group which has a common table This was the position in Wuppertal when we were there in 1946–47 When a small present of food was taken to someone in a German family it was obvious that everyone in the household would have the chance of sharing it, but the parcel was at once concealed if the doorbell rang for another visitor—all very reminiscent of the undernourished rats When famine gets very bad it tends to become a matter of every man for himself The behaviour of the " population " as a whole depends upon its morale If this is good—and it has been very good in many of the picked parties of explorers who have run short of food (Shackleton 1909, and see Keys Brozek et al 1950)—this last stage may be postponed almost indefinitely It probably developed most rapidly and was to be seen at its worst in the concentration camps, where group loyalties were almost non existent " Fights and flogging practically always attended the distribution of food, calling to mind the feeding of animals at the zoo " (Helweg-Larsen et al 1952) Whatever the morale, standards of behaviour always tend to fall with the supplies of food Black-marketeering, thieving, plunder, and even murder become commonplace events and no power on earth can prevent them

In the last stages people may become completely apathetic to all that goes on around them They lose all their self-esteem, their interest in their neighbours, male or female, and even in the struggle for food When this happens the end is not very far away

Closing Reflections

Hitherto research on nutrition has been directed largely by circumstances or economic reasons Wars have led to widespread undernutrition, prosperity has filled the clinics with preventable obesity—and consequently both have been studied Animal husbandmen have bred and fed their animals for rapid maturity and marketable [illegible] and political husbandmen have come near to doing the same for children Curiously little thought has been devoted to a study of the plane of nutrition for the different years of endeavour

Why such a plane should be desirable and achieve it have been still less considered Yet, by the figures for infantile mortality, the child of size at the time of delivery stands a better survival than an underdeveloped one or one which grown too great in utero The reasons are often enough, but how to produce the happy mean matter It would, however, be a minor preventive medicine if all babies could be delivery weighing between 6½ and 7½ lb We define the desirable levels of nutrition later in life, yet how they can be achieved They have not studied realistically Haldane (1940) once wrote essay " on being the right size " One day someone write a book " on being in the right plane of There is one, that is certain, for every age, but necessary to drink 500 ml of milk a day throughout or to eat 50 g of animal protein in order to Some politicians are sure it is, but I am not hope not, for I see no hope of providing the millions of this world with either of these good

I have a feeling that we should think of how to that happy mean in matters of nutrition which enable us to reduce infantile mortality and to the vigour of life from being weakened by the onset of old age *μηδὲν ἄγαν* may well turn out the legend for one of the signposts on the road to health

These lectures have been prepared jointly with Dr Widdowson I have had the privilege of delivering if they have any merit, half of it is due to her

TRANSFUSION BY THE INTRA-ARTERIAL ROUTE

ALLAN S BROWN
M.B Edin., F F.A.R.C S

CONSULTANT ANÆSTHETIST DEPARTMENT OF SURGICAL NEUROLOGY ROYAL INFIRMARY EDINBURGH

THIS paper is based on one read in 1951 before the Association of Surgeons of Great Britain and Ireland its purpose is to indicate the benefits, in certain circumstances, of retrograde intra arterial transfusion and to discuss the possible dangers if solutions other than blood are used

The history of intra-arterial transfusion dates back to the beginning of this century Nearly fifty years ago Crile and Dolley (1906) showed that retrograde arterial perfusion with Ringer's solution to which adrenaline and hirudin had been added would consistently restart a heart stopped by an overdose of chloroform or ether This response was elicited up to 5 minutes after cardiac arrest and despite the failure of cardiac massage

This fact supported the findings of Sollman (cited by Crile and Dolley 1906) who postulated that the initiation of cardiac action depended on raising the coronary perfusion pressure to 30 or 40 mm. Hg and was not influenced by the quality of the perfusing fluid indeed Sollman restarted the heart in physiological preparations by perfusing the coronary arteries with mercury Once cardiac action had been initiated however the quality of the perfusant was important if the heart beat was to continue

Little attention seems to have been paid to these findings, for few references to arterial perfusion were published before Kemp (1933) suggested that retrograde arterial perfusion with physiological saline solution should be tried in man as a heroic measure to restart the heart after cardiac arrest during an operation

This method of treatment again lapsed into obscurity until Birillo (1939) and Negovsky (1945) claimed considerable success with it Since then several short papers have appeared, mainly in America each claiming that retrograde arterial perfusion has advantages over the normal intravenous route but almost all emphasising the danger that local gangrene might follow its use (Kohlstaedt and Page 1943 Porter et al 1948 Page 1947 Haxton 1952 Devitt and Widgerow 1951 Bayles 1951 Bingham 1952)

While trying to produce by bleeding a controllable level of circulatory depression in dogs, Kohlstaedt and Page (1943) found that the resulting hypotension could be more satisfactorily treated by intra arterial than by intravenous replacement of blood.

Clinical Evidence

Experience in the departments of anæsthetics and surgical neurology of Edinburgh University concerns cases in which retrograde intra arterial injection is used to replace blood purposely withdrawn in the technique of preoperative exsanguination or lost accidentally when large vessels are torn during the removal of a vascular tumour

For the past four years preoperative bleeding of the patient has been used as an aid in certain intracranial operations Following premedication with Nembutal gr 3 and atropine gr $^1/_{100}$ an hour before the operation anæsthesia was induced with thiopentone 0·5 g., and the larynx was intubated under direct vision anæsthesia being maintained with nitrous oxide and oxygen

After infiltration of the surrounding tissues with 2% procaine solution the radial artery was exposed through a small transverse incision over the artery about 2 in proximal to the radial styloid process. The artery was tied a small incision made in the vessel proximal to this ligature and a cannula inserted which was connected to a damped aneroid manometer and the blood-taking and transfusion set and was kept free from clots with intermittent injections of 1% sodium citrate solution in saline solution

When the operation was about to start, blood was rapidly withdrawn into a bottle containing the appropriate amount of sodium citrate until the desired degree of reactionary vasoconstriction was produced This was usually achieved by the withdrawal of 500–1000 ml, the systolic blood-pressure falling to about 80–90 mm Hg and the pulse rate rising to not more than 120 The blood pressure was maintained at the desired level by the addition or subtraction of such volumes of blood as were necessary The blood-pressure was recorded directly from the manometer connected to the radial artery as well as by auscultation over the brachial artery of the other arm

During the infusion of blood there was no recon
change in blood-pressure except for a very transient
of about 5 mm Hg at the start and a momentary c
parable fall on its completion Thereafter the bl
pressure remained constant for 2–5 minutes and t
rose to a new level over the next 10 minutes

Even after prolonged hypotension, lasting up t
hours or more, the addition of a relatively small vol
of blood intra-arterially was often sufficient to raise
systolic pressure from 70 to 80 mm Hg

In an attempt to compare the responses to intra
and intra arterial injection, transfusions of 100
blood were given at the rate of 8 ml a second. In
case the intravenous injection preceded the arterial
by half an hour, during which the patients' circu
responses were recorded A similar observation pe
followed arterial transfusion

On a few occasions when blood was not available a ɔid intravenous infusion of plasma was used in an empt to combat the effects of a sudden massive morrhage In those cases in which hypotension had ɔn severe and lasted for 5–6 hours the patients ponses to intravenous therapy were unsatisfactory In o particular instance the patient's condition was affected by the rapid intravenous administration of)0 ml of plasma An hour later 150 ml of blood was ven by the retrograde arterial route, whereupon there s an immediate and sustained rise in blood pressure th a fall in pulse rate. Plasma was not given intra erially, for reasons given below

Even with rapid rates of injection—e g 8 ml a second no sign of cardiac embarrassment was noted until the imated restoration of blood volume was complete ıen the pulse suddenly slowed the blood pressure fell nsiderably, and there was pronounced peripheral vaso atation These circulatory changes were reversed ontaneously and completely within 2–3 minutes after e transfusion had been stopped.

Plethysmographic Studies

As already stated, the response to intra-arterial trans sion usually appeared after a delay of 2–5 minutes In attempt to discover what was happening during this ent period, plethysmographic records were made from ı consecutive cases, and seven satisfactory plethysmo ams were obtained The three other tracings were scarded either because they were marred by technical ılts in the equipment or because severe circulatory sturbances had appeared as a result of interference with e basal structures of the brain

It was decided to estimate the blood flow through the ; and foot, although it was known that this method of easurement had been abandoned several years ago ıder conditions of altered blood volume the vessels of e skin, which is a large and not unimportant organ ust exert a considerable influence For the purpose of mparison the first two cases had simultaneous record gs made with the foot occluded and with the foot culation intact. The difference noted appeared to be ıe of degree rather than response.

Plethysmograms were recorded by the method scribed by Barcroft and Swan (1953)

sults

The results obtained in seven of the cases are set out the accompanying table Blood flows were estimated percentages of the initial blood flow

In one case, after a prolonged period of reactionary soconstriction, the plethysmogram altered from the ual triangular shape becoming trapezoidal in outline. his appearance coincided with the disappearance of ıe superficial veins, the normal triangular tracing appeared when the superficial veins began to be visible ıce more This alteration was not due to faulty record g but was probably due to a severe reduction of the ripheral vascular capacity brought about by intense soconstriction

Discussion

Retrograde arterial transfusion has been used success ılly in 105 cases Whereas intravenous and intra *rterial transfusions are equally effective in patients* who ıve suffered blood loss and hypotension for brief eriods, they differ when the latter conditions are more rolonged the patient failing to respond adequately) intravenous therapy A refractory state develops in hich there is a less satisfactory response to intravenous ıan to intra arterial infusions.

It may be asked why arterial transfusion should be ıccessful when intravenous therapy is not, and why the eaction to equal amounts of blood given by the two outes should differ both immediately and later

When oligæmic shock has developed after severe hæmorrhage, some patients show a satisfactory initial response to intravenous infusions, which however is maintained for only a few hours This happens even if the circulating blood volume has been restored to normal.

It appears that circulatory failure following severe hæmorrhage or injury has two components : a failure of vasoconstriction to compensate adequately for the reduced circulating blood volume and a "central factor" probably due to a failure of the heart to act as an efficient pump under normal conditions of venous return and filling pressure

In patients who have been temporarily resuscitated by adequate intravenous therapy the peripheral mechanism can still work for a reasonable circulation is maintained for several hours before the patient again passes into the state of circulatory failure.

Wiggers (1947) has shown that rapid intravenous transfusion is followed by an increase in venous return and cardiac output, but that the auricles and ventricles are considerably distended working under abnormal conditions of filling As the venous pressure falls after the transfusion is stopped, cardiac output declines, and so the patient again develops circulatory failure This is the *state of so-called irreversible shock and Wiggers showed* that the myocardium was significantly depressed The cardiac output was therefore reduced for a normal degree of filling and hence stimulation

In the less ill patient in whom circulatory failure is present but where successful resuscitation follows adequate intravenous transfusion, probably the "central" insufficiency has not yet developed to a serious degree. In this case the most important factor has been the inability of reactionary vasoconstriction to maintain an adequate circulation, because of an excessively reduced circulating blood volume, correction of which alone is sufficient to allow restoration of a normal circulation

In several published reports it has been postulated that retrograde arterial perfusion will raise the pressure in the arterial tree including the aorta, according to physical laws without having to presuppose any other less tangible theory This rise would lead to an increased coronary perfusion pressure, and accordingly improved *nutrition of the myocardium restoration of the efficiency* of the heart, and so correction of "central failure."

This suggestion by ignoring the vasodepressor responses from the aortic arch and the carotid arteries assumes that there is no alteration in peripheral resistance during transfusion for if there is any change, there may be no significant alteration in blood pressure.

No alteration in blood pressure during intra-arterial transfusion could be demonstrated in any of the cases under review apart from the very transient rise and fall of some 5 mm Hg at the start and end of the transfusion This minimal and extremely brief fluctuation hints at a readjustment in the operation of the vasomotor compensating mechanisms

Plethysmograms showed that the blood flow measured below the knee during the transfusion was increased 2–5 times, and that the flow returned to the pre transfusion level immediately the administration was stopped 2–3 minutes later the recordings indicated a progressively increasing blood flow before there was any change in blood pressure

The plethysmograms showed that there was a difference in the response to the administration of small quantities of blood between the intravenous and retrograde arterial routes, the response being greater and more prolonged after arterial transfusion Indeed after all but the shortest periods of reactionary vasoconstriction no response could be demonstrated after the intravenous administration of small quantities such as 100 ml., of fluid whether blood plasma, or other substitute

It will be appreciated that it is difficult to draw absolute conclusions from plethysmograms, but the interpretation of the tracings obtained, along with simultaneous blood pressure recordings, suggest that almost immediately after the initiation of arterial transfusion there is a decrease in the degree of peripheral vasoconstriction. Vascular tone returns to the pre-transfusion level immediately the injection of blood is terminated, to be followed within 2–3 minutes by a further decrease of vasoconstriction and, in the presence of an unaltered blood-pressure, an increase in cardiac output. A rise of blood-pressure only occurred several minutes after the first change in peripheral blood-flow had become apparent.

This response has usually been seen within 5 minutes of the end of the arterial transfusion, although in ten cases the response was less than anticipated. These latter were all cases in which a protracted period of severe hypotension had been maintained. With the giving of further quantities of blood over the next 10 minutes the circulation was permanently restored and maintained at an adequate level.

It has not been possible to demonstrate the mechanism whereby permanent resuscitation follows intra arterial transfusion whereas under equally critical conditions intravenous therapy produces only temporary improvement. It seems reasonably certain that the difference in results depends on restoration of the efficiency of the heart, and it is surprising that an intra arterial transfusion of 100–200 ml of blood, lasting only about 30 seconds, can initiate such a dramatic change. That a permanent change is brought about, however, is beyond dispute.

Dangers

Either arterial or venous “bank” blood may be used as the perfusing fluid. On one occasion 100 ml of physiological saline solution was injected, and the whole arm assumed a waxy hue from the finger tips to the axilla, nearly 5 minutes elapsed before a normal appearance returned to the limb.

To perfuse a limb with a non oxygen carrying fluid is to court disaster. Even in severe circulatory failure the patient's blood contains oxygen which is utilised by his tissues, but if plasma, saline, or other blood substitute is used, this solution will produce a rapid anoxia of the perfused tissues, which may be sufficient to cause local necrosis. This is probably of significance because all but two of the cases of gangrene published occurred after the use of plasma or of saline solution. Of the two exceptions, one case of gangrene was due to an anatomical abnormality in the arterial supply of the hand, there being no radial ulnar anastomosis, and the other was attributed to reflex spasm of the radial artery induced by the escape of blood into the tissues.

In the present cases the radial artery was routinely tied in continuity, the only complication met so far has been a mild blotching of the skin for a few hours over the area of distribution of the radial artery.

Conclusions

In civilian practice intra arterial transfusion should probably be restricted to the preoperative treatment of patients in whom there has been a considerable reduction of circulating blood volume and when there is no satisfactory response to intravenous therapy after a brief period of adequate trial.

Intra arterial transfusion is of value during those operations in which uncontrollable and massive hæmorrhage is likely—e g, in certain operations on the brain and the heart.

In military practice, when supplies of blood may be limited and time short, this method may be preferred to intravenous therapy, for it has been shown experimentally, as well as clinically, that a small quantity of blood
given by the retrograde arterial route has a vastly gr
effect than an equal amount of blood given intraveno
Once the desired effect has been achieved, the
transfusion can be discontinued, and plasma or
substitute administered intravenously to rest
patient's blood volume.

When the advantages of this method of treatm
suitably selected cases are compared with the disa
tages, the latter appear to be small. The risk of
following ligation of the radial artery at the wri
very slight, and to take such risk is justifiable in d
with cases in which life may depend upon the abili
resuscitate the patient.

In severe circulatory failure it is doubtful wheth
will take longer to expose and cannulate an artery
a vein shrunken and emptied by reactionary
Nevertheless it may be difficult to cannulate the r
artery under conditions of extreme vasoconstriction
occasionally it may be necessary to insert a needle
the femoral artery or even into the aorta.

We have never yet met conditions in which reactio
arterial spasm involving the limb prevented the inje
In those few cases in which there was difficulty
was restricted to a segment of the vessel about 2 cm.
at the site of insertion of the cannula. It was m
overcome by applying 2% procaine solution to
affected segment. Spasm is readily caused by
handling of the artery or as the result of using too
a transfusion pressure.

Summary

In the data collected from 165 cases there is
that intra arterial transfusion is of advantage in
treatment of patients who have become exsan
to critical levels, or are in severe circulatory f
other reasons, it is unnecessary and unjustifiable
the blood loss is small.

I am grateful to Prof Norman Dott for his
and assistance during this investigation, and to Dr
Gillies and Prof David Whitteridge for their help in
this study and for their valuable criticism in assessin
results.

HYALINE MEMBRANE IN THE NEONATAL LUNG

ALBERT E CLAIREAUX
M.D Edin., M.R C.P E
ID ANATOMIST BERNHARD BARON MEMORIAL RESEARCH
ORATORIES QUEEN CHARLOTTE S MATERNITY HOSPITAL
AND INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY
HAMMERSMITH HOSPITAL, LONDON

E of the great dangers of early neonatal life is the re of the lungs to expand fully This failure may from the time of birth (primary atelectasis) or rying degree of expansion of the lungs may be wed by collapse (secondary atelectasis)

electasis, whether primary or secondary is very ently encountered in premature infants and is d the most important single cause of death among Though the use of antibiotics has greatly reduced prevalence and severity of respiratory infections in neonate, death from respiratory failure is still non in the premature infant The clinical features electasis neonatorum, and some methods now being ed to combat it have lately been described by ld and Lord (1953)

the pulmonary abnormalities found in association atelectasis in the newborn the most striking e presence of a hyaline membrane This peculiar brane was first noted by Hochheim (1903) and described more fully by Johnson and Meyer (1925) latter were chiefly interested in pneumonia in the orn and in the relation of this membrane to pul ary infection *There has been considerable con* n over its ætiology and significance and the subject viewed in detail by Tran Dinh De and Anderson 3)

view of the importance of atelectasis as a cause of h in the newborn, the development of a hyaline brane seemed to merit further investigation Accord I have reviewed the histological preparations from lungs of all infants examined post mortem at the n Charlotte s Maternity Hospital and Hammersmith pital in the five years 1948–52 inclusive In all, 2500 blocks of lung tissue have been studied.

Findings

INCIDENCE OF HYALINE MEMBRANE

ut of 810 necropsies on stillbirths and neonatal hs 108 cases were found to show hyaline membrane as then noted that none of the infants in which it rred had been stillborn The membrane had efore developed in 108 (29%) of 376 liveborn infants incidence similar to that reported by Bruns and lds (1951), Tregillus (1951) and Blystad et al. 1) Only Miller and his associates (1949 1950) reported hyaline membrane in stillbirths

f the 108 infants with hyaline membrane 76 were es and 32 females (male preponderance 2·4 1)

ELATION OF MEMBRANE TO MATURITY OF INFANT

he cases may be grouped according to their birth ghts as follows:

500–1000 g	12	2001–2500 g	15
1001–1500 g	36	Over 2500 g	22
1501–2000 g	23		
		Total	108

ill be seen that only 22 (20%) weighed 2500 g or r Thus hyaline membrane occurs chiefly in premature nts.

TIME AND CAUSE OF DEATH

he ages of the infants dying with membrane in the g were:

0–12 hours	44	37–48 hours	13
13–24 "	27	Over 48 "	12
25–36 "	12		
		Total	108

It will be seen that 71 (66%) died in the first 24 hours The earliest death was at $1^1/_2$ hours and the latest at $6^1/_2$ days 4 other infants lived for 6 days

The main causes of death were

Hyaline membrane only	81
Subdural hæmorrhage	9
Intraventricular hæmorrhage	7
Hæmolytic disease	5
Pneumonia	4
Intrapulmonary hæmorrhage	1
Hydrocephalus	1
Total	108

Hyaline membrane was the sole pathological lesion in 81 cases (75%) Intracranial (subdural) and intra ventricular hæmorrhage were the next commonest causes Intraventricular hæmorrhage is not infrequently asso ciated with atelectasis and the formation of hyaline membrane It is to be regarded as the result of anoxia rather than of birth trauma There were only 4 cases of pneumonia. Of the 22 infants weighing 2500 g or more, 7 were postmature, 4 were delivered by cæsarean section, 3 suffered from hæmolytic disease 1 had hydro cephalus, and 6 had severe subdural hæmorrhage follow ing difficult forceps deliveries Thus 10 (45%) had some pathological disorder 4 (18%) were delivered by section and only 1 had a normal gestation and delivery Although this group of 22 infants were not subject to the hazards of prematurity they could not be regarded as normal healthy infants at the time when hyaline membrane was formed

INCIDENCE OF CÆSAREAN SECTION

As Potter (1952) has remarked hyaline membrane often occurs in infants delivered by cæsarean section *In the present series of 108 cases 22 infants* (20%) were delivered by section The period of gestation at which section was carried out, and the reason for the section are shown in the accompanying table The 4 infants weighing over 2500 g were delivered by section at 38 weeks By far the most important reason for section was severe pre-eclamptic toxæmia—13 cases (59%) Ante partum hæmorrhage with or without placenta prævia accounted for another 5 cases (23%) One in every five of the hyaline-membrane cases had been delivered by cæsarean section

CÆSAREAN SECTION

Reason for section	No	Period of gestation	No
Pre-eclamptic toxæmia	13	20–30 weeks	5
Antepartum hæmorrhage	2	31–34 weeks	11
Placenta prævia	3	35–38 weeks	5
Diabetes	3	Term	1
Contracted pelvis	1		
Total	22	Total	22

ABNORMALITIES IN THE MOTHER

There were 104 mothers of the 108 affected infants There were 4 pairs of twins and 14 other twins whose partners survived Thus twin pregnancy occurred in 18 of the 104 pregnancies (17%) There was one triplet in the series 31 (28%) of the mothers were primi parous The pregnancy had been terminated in 8 cases by artificial rupture of the membranes In 7 cases forceps delivery had been carried out and in 6 of these severe subdural hæmorrhage had occurred in the infant External version before delivery had been done in 2 cases. The presentation was vertex in 69 cases and breech in 17 the remainder being delivered by section

If multiple pregnancy is regarded as abnormal there was some abnormality during pregnancy in 69 women (66%)

In addition to the 19 instances of multiple pregnancy there were 19 cases (18%) of pre-eclamptic toxæmia. There were 11 cases of antepartum hæmorrhage and 5 cases of rhesus iso immunisation There were 3 cases of severe heart-disease (1 of mitral stenosis 1 of paroxysmal tachycardia and 1 of patent ductus arteriosus) In 3 patients who came to premature labour there had been a threatened abortion earlier in preg

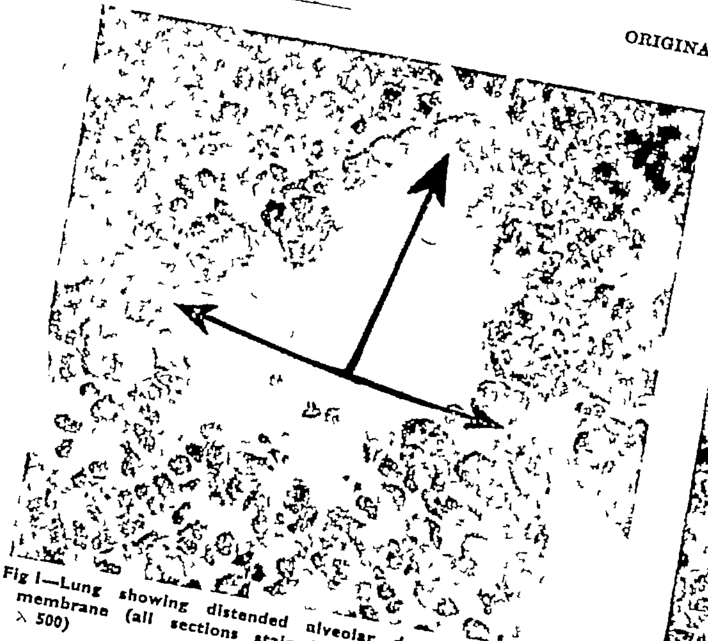

Fig 1—Lung showing distended alveolar duct lined by hyaline membrane (all sections stained with hæmatoxylin and eosin × 500)

nancy (2 at 8–12 weeks and one at 16 weeks) There were 3 cases of diabetes, 2 of bicornuate uterus, 2 of tuberculosis, 1 of syphilis, and 1 of nephrosis

ILLNESS IN THE INFANT

The clinical features of hyaline membrane formation have been fully described by Donald and Lord (1953) The infant is usually premature and there may be some difficulty in establishing respiration The air entry is poor and after an hour or two marked rib-recession develops There are cyanotic attacks and periods of apnœa, and the infant dies within 24–48 hours of birth

PATHOLOGICAL CHANGES IN THE LUNGS

On naked eye examination the lungs are bulky and dark red They show little evidence of aeration, and both lungs and each of their lobes usually sink when placed in water On being sliced, the lungs are seen to be airless, congested, and of the consistence of liver

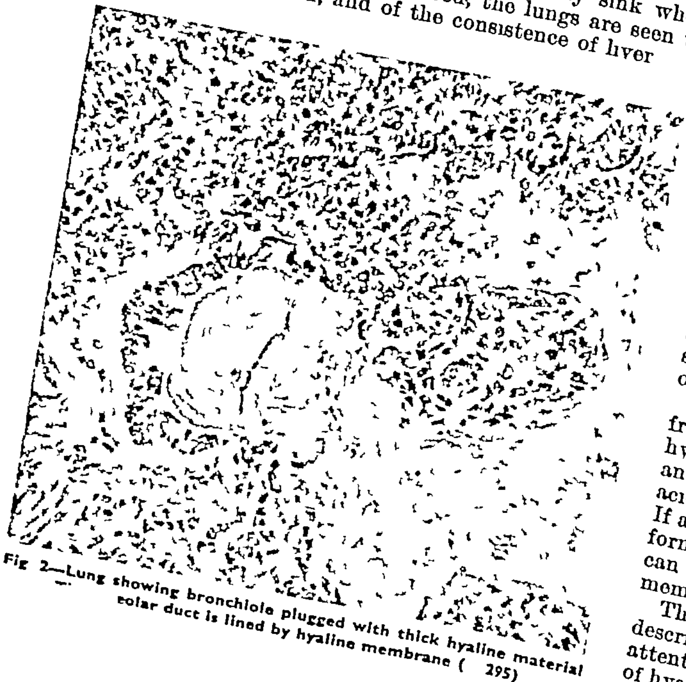

Fig 2—Lung showing bronchiole plugged with thick hyaline material eolar duct is lined by hyaline membrane (× 295)

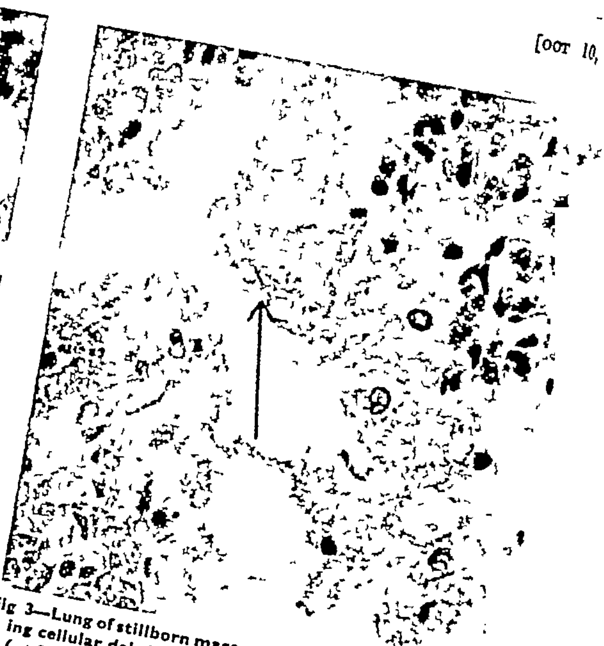

Fig 3—Lung of stillborn macerated fœtus showing alveolar du ing cellular debris and triangular plug of acidophil hyalin (× 380)

When examined histologically, the lungs have a appearance The greater part of the parenchym collapsed and the alveolar capillaries are eng Alternating with these atelectatic areas are a numb structures which appear to be overdistended Thes mainly alveolar ducts and respiratory bronch On closer examination these ducts and bronch are seen to be lined by dense hyaline material wh strongly acidophil when sections are stained hæmatoxylin and eosin This is the so-called hy membrane (fig 1) It is found chiefly lining ducts but also along the walls of some alveoli a bronchioles It does not stain for fibrin and weakly positive reaction with the periodic aci technique indicating the presence of a polysacc Often, but not always, neutral fat can be detec this membrane In spite of the use of a wide of special stains, the exact histochemical nature of hyaline membrane has not yet been determined

A study was made of some 450 blocks of lung t obtained from the 108 cases It was quickly re that the membrane is not quite so homogeneous i sections as was once thought In nearly ever some of the sections showed areas where the memb was less evenly distributed round the walls of ducts or was fragmentary The membrane ir areas seemed to be in process of formation and noticeable that it had a more precise structure less homogeneous than the fully formed materia seemed to be *cellular* In hæmatoxylin and sections the cells were bright red, and the faint o of a nucleus could sometimes be made out

The cells were then identified as flat squames from the liquor amnii Groups of these hyaline cells clump together, lose their cellular and cellular identity, and fuse to form the acidophil membrane lining the air spaces in the If a sufficient number of blocks are taken this progres formation of hyaline membrane from individual squ can be traced in nearly every lung containing h membrane

The transition from squames to membrane described by Johnson and Meyer in 1925, but attention has been paid to this aspect of the path of hyaline membrane More recently Miller and Ham (1949) noted the presence of certain cells in the neigh d of developing hyaline membrane They believed t these cells were responsible for the membrane nation but were unable to identify them Since the s were bright red and not basophil they rejected the that they might be squames from the liquor amnii my opinion, however they are indeed squames ch have become progressively more acidophil and line while lying in the air-spaces of the affected lungs n a number of cases plugs of hyaline acidophil terial are found in some of the alveolar ducts and piratory bronchioles (fig 2) These plugs are formed the fusion of groups of hyalinising squames but not dispersed round the walls of the air spaces in the n of membrane Nuclear remnants can sometimes identified These plugs may be very large, and directly blocking the airways they may be partly onsible for atelectasis The process of hyalinisation squames is not confined to liveborn infants small gs of similar material may be found even in the cerated fœtus (fig 3) Membrane formation does occur before birth, however because there is no air to perse the squames to the periphery of the air-spaces astly, typical cornified cells derived from the liquor nii can be found in most sections. These may be ttered in the lumen of the alveolar ducts and alveoli may be caught in the membrane itself They do seem to fuse into amorphous masses like the hyalinised ames. This may be because they are keratinised l cannot undergo the chemical change necessary complete hyalinisation

EXPERIMENTS

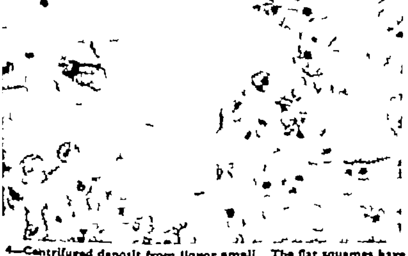
hese histological findings suggested that the primary tor in the production of hyaline membrane is aspiration iquor amnii

o substantiate this explanation samples of liquor nii were examined by chemical and histological thods An attempt was made to reproduce hyalinisa n in vitro And finally the reproduction of a hyaline mbrane in an animal was achieved

EXAMINATION OF SAMPLES OF LIQUOR AMNII

total of 40 specimens from separate pregnancies s examined.

6 of these specimens were obtained at term 10 were from t mature pregnancies and 4 were from premature deliveries. The amount of fluid in each specimen varied greatly for some of the specimens were from cases of hydramnios and 4000 ml or more was obtained Each specimen was centrifuged and the amount of sediment measured This amount varied from 0·1% to 7 2% by volume (average 1 9%): at 14 weeks and 25 weeks it was 0 1% and at 32 weeks it was 0 4%, indicating that the amount of solid material increased greatly as pregnancy advanced. This was as expected The protein content of the supernatant fluid was estimated. This varied from 40 to 300 mg per 100 ml with an average of 128 mg



4—Centrifuged deposit from liquor amnii The flat squames have faintly basophil cytoplasm and dark-blue central nucleus (× 300)

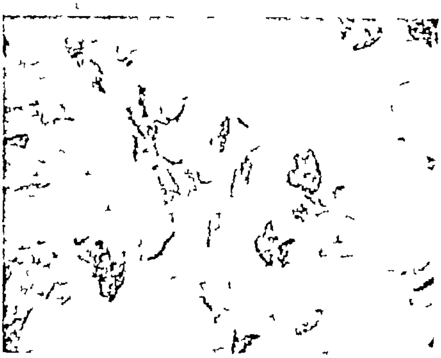


Fig 5—Centrifuged deposit from liquor amnii after 8 days incubation. Cells are more acidophil and nuclei have been lost (× 300)

Smears of the centrifuged deposit were fixed in alcohol and stained with hæmatoxylin and eosin The solid material was seen to consist of innumerable large flat squames which had a slightly basophil cytoplasm and a large dark central nucleus (fig 4) Varying numbers of cornified cells were also present. Paraffin sections of the centrifuged deposit had an appearance similar to that of the smears.

To simulate the hyalinisation which seemed to occur in the infants lungs samples of centrifuged liquor deposit were resuspended in an equal volume of saline and incubated at 37 C After 7–10 days the squames had lost their nuclei and had become strongly acidophil (fig 5) Some of the cells had coalesced to form hyaline masses not unlike those found in lung sections The incubated material now seemed to be in a favourable state for the production of a hyaline membrane and further experiments were made

EXPERIMENTAL PRODUCTION OF A HYALINE MEMBRANE

During the above investigation it was noted that some samples of liquor amnii did not centrifuge well, and that the supernatant fluid contained opaque tenacious white material This material contained numerous cornified cells but few flat squames, and this type of liquor was judged unsuitable for experiments

When a favourable sample of liquor amnii had been obtained by high artificial rupture of the membranes under aseptic conditions, the fluid was centrifuged Aliquot parts of the deposit were resuspended in equal volumes of sterile normal saline to which chloramphenicol 65 µg per ml. had been added. The suspensions were then incubated at 37°C for 8 days At the end of the incubation period smears were examined to make sure that hyalinisation of the squames had occurred The suspensions were then centrifuged and the deposit carefully ground in a sterile virus grinder to secure a completely smooth suspension To 0 5 ml of this deposit was added 0 5 ml sterile saline containing chloramphenicol 65 µg per ml. This material was then injected intratracheally into six young albino rats (weight 175 g) A further rat received an intratracheal injection of 1 ml sterile suspension of the deposit from the same fluid, but the deposit in this case had not been incubated

The rats which had received the injection of incubated material were killed at 1, 2, 3, 5, 24, and 29 hours The seventh rat was killed after 24 hours

RAT 1 (killed at 1 hour) —Hyaline material and some cornified cells were plugging the bronchi and bronchioles There was moderate collapse in the upper lobe of the right lung which was chiefly affected Some of the alveolar ducts were lined with hyaline material

RAT 2 (killed at 2 hours) —Hyaline material was seen in bronchi and bronchioles with a varying degree of atelectasis of the surrounding lung parenchyma Many alveolar ducts were lined by acidophil hyaline material which was forming a membrane Some cornified cells were seen in many areas

RAT 3 (killed at 3 hours) —Many bronchioles were plugged by acidophil hyaline material (fig 6) There was severe collapse of the surrounding lung parenchyma, especially in the upper lobe of the right lung where areas of collapse were evident on naked eye examination Some overdistended alveolar ducts were seen to be lined by acidophil hyaline membrane (fig 7) This membrane was exactly comparable to that found in the lung of an infant (fig 1) A moderate polymorphonuclear leucocyte reaction was observed in some areas

RAT 4 (killed at 5 hours) —The injection had been unsatisfactory and only scattered clumps of hyaline material and cornified cells were found

RATS 5 AND 6 (killed at 24 and 29 hours) —Findings as in rat 3 The increased duration of the experiment had little or no effect on the outcome

RAT 7 (killed at 24 hours) —This rat received the material which had not been incubated No areas of collapse were evident macroscopically Histologically a few small atelectatic areas were present Many bronchioles were plugged with cornified cells and similar cells were present in neighbouring alveoli There was some overdistension of alveolar ducts in the collapsed areas and occasional collections of cornified cells against the duct walls These bore a faint resemblance to hyaline membrane, but such aggregations were very small and the picture was in no way comparable to that found in rat 3

This experiment showed that suitable treated deposit from the liquor amnii will produce an acidophil hyaline membrane when injected intratracheally into a rat. membrane thus formed lines bronchioles and al ducts in the same manner as the membrane found lungs of infants It is acidophil with hæmato and eosin staining, and fat droplets were seen in th sections stained with Scharlach R

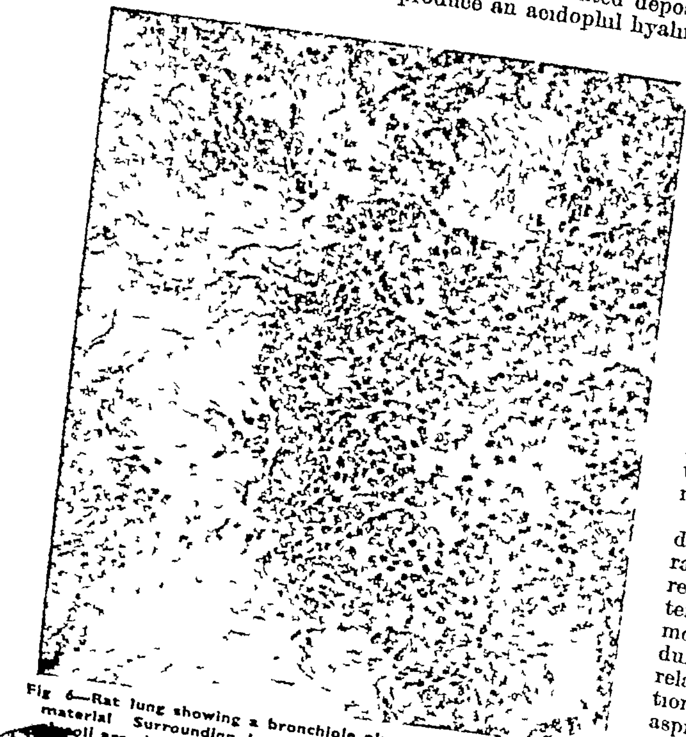

Fig 6—Rat lung showing a bronchiole plugged by acidophil hyaline material Surrounding lung is completely collapsed and some alveoli are also plugged with this material (× 340)

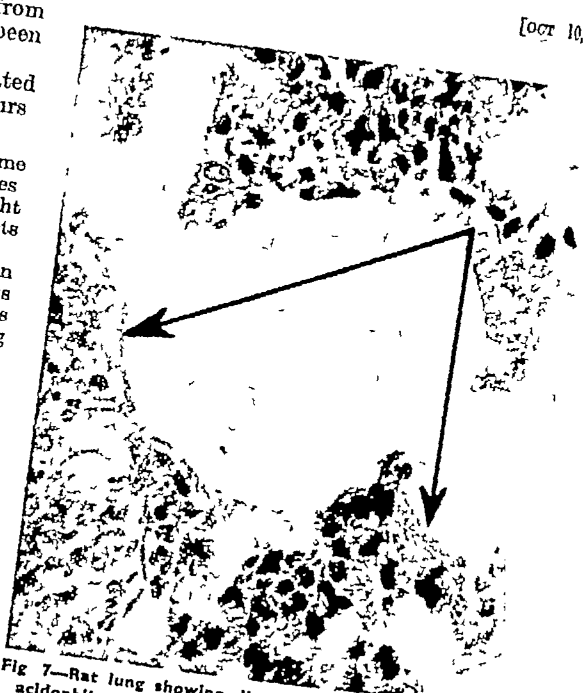

Fig 7—Rat lung showing distended alveolar duct partially acidophilic hyaline membrane Surrounding lung is collaps few of the alveoli contain plugs of acidophil material (× 34

Discussion

In this survey of 108 cases of hyaline membrane fo tion the majority of affected infants were p a finding similar to that of other workers Of affected infants who were born at term or post ma the majority had some other pathological lesion subdural hæmorrhage or hæmolytic disease) which them, like premature infants, less able to deal aspirated liquor amnii Moreover, circumstances sometimes have led to their inspiring an unduly quantity of liquor For example, it is well known t as the infant is extracted from the uterus by section it is inclined to take a gulp of liquor and we may note that of the 108 infants in this 22 were delivered by section, but it is only fair t out that 16 of these (73%) were delivered bef 35th week and so were premature

It has also been pointed out that 50 of the m had some abnormality of pregnancy—the being pre eclamptic toxæmia—and that a furthe had a multiple pregnancy These abnormalities to increase the risk of premature delivery and thus risk of developing a pulmonary hyaline membrane

The reason why premature infants are more pro develop this membrane than mature infants re rather obscure It is possible that the premature inf respiratory centre is more sensitive to changes in o tension and that intra uterine respiratory efforts o more easily In response to anoxia, either before during delivery, the premature infant may as relatively large quantities of liquor amnii The cu tion in the premature infant's lung is less able to al aspirated fluid than is the mature infant's and squames deposited in the air passages are in fact incub in a fluid medium which allows hyalinisation to p When the infant is delivered and begins to bre the hyalinised material is dispersed round the he air passages in the form of a membrane It is possible that the liquor amnii at 28–36 weeks ation contains a relatively high proportion of non tinised squames which are unusually susceptible to process of hyalinisation This possibility requires her investigation.

fter aspiration the squames deposited in the lung ergo progressive hyalinisation This may be well anced by the time the infant is delivered since nbrane formation has been detected in an infant ng $1\frac{1}{2}$ hours after birth

arber and Sweet (1931) suggested that the membrane formed as a result of aspiration of vernix caseosa e it gave a positive reaction for fat. But in fact ny hyaline membranes contain little or no fat If any given case the squames involved in membrane nation are derived from vernix and covered with fat n, and then only will the membrane give a positive tion with fat stains This explains the varying ilts from case to case where fat stains are employed

lystad et al (1951) suggest that the liquor is absorbed the lung of the newborn infant but the protein is left ind in the air-spaces as this protein gradually centrates, it is laid down as a membrane lining the ls of alveoli and alveolar ducts It is probable that h concentration of protein does occur, and that it s to the thickness of a membrane already formed by hyalinisation of squames It is unlikely to be respon e for the formation of the entire membrane which is n very thick

telectasis is the cause of the infant's death In the eriment on rats the atelectasis was largely the result plugging of the respiratory bronchioles and mouths of eolar ducts with thick hyaline material In the infant mechanism is also at work but other factors are also olved. In the infant's lung hyaline membrane is ch more widespread than any yet produced in the erimental animal. (This is partly because the infant utero can aspirate fluid into all branches of the nchial tree whereas a corresponding injection of d into the bronchial tree of rats would probably ult in rapid death from asphyxia.) The membrane ering numerous alveolar ducts in the infant's lung erferes with the gaseous exchange and prevents air ching the more distal air-spaces which become npletely collapsed But at birth the hyaline material probably not in the form of a membrane and air is e to reach the distal alveoli The pressure of air forces material against the walls of bronchioles and alveolar ts and this eventually seals off the distal air-sacs s explains how some infants seem to breathe reason y well shortly after birth but their respiration omes progressively more laboured until death ensues

he present study indicates that massive aspiration liquor amnii is the prelude to formation of hyaline mbrane. The infants thus succumb to an unusual form drowning While the fluid is largely absorbed into the lmonary circulation, the mud left behind in the form hyalinised squames eventually covers the walls of the eolar ducts and leads to death by suffocation

Summary

Hyaline membrane was found in the lungs of 108 t of 370 liveborn infants who died in the early neonatal riod.

It is suggested that this membrane is formed from uames in the liquor amnii The liquor is aspirated o the fœtal lung and the squames undergo progressive alinisation and fusion

Suitably treated deposit from human liquor amnii, ien injected intratracheally into the rat, will produce hyaline membrane in the animal's lung

The atelectasis associated with hyaline membrane in e newborn infant is partly the result of direct obstruction of the airways by plugs of hyaline material and partly the result of air being trapped in the distal air-sacs when the alveolar ducts are sealed by membrane

I am indebted to Dr J Murray for much advice and criticism I wish to thank Dr G H Lathe and his staff for undertaking the chemical investigations and for considerable help with the experiments. I am grateful to Mr Ian Donald for much coöperation on the clinical and physiological aspects of this work, and to the obstetric staffs of Queen Charlotte's and Hammersmith Hospitals for obtaining samples of liquor amnii The photomicrographs were prepared by Mr E Clark of Queen Charlotte's Hospital

GASTRIC RESECTION

FOR GASTRODUODENAL HÆMORRHAGE WITHOUT AN OBVIOUS ULCER

Gordon Ferguson
M.B N.U.I F.R.C.S

SENIOR SURGICAL REGISTRAR, HASTINGS HOSPITAL GROUP SUSSEX

Now that surgery plays an increasing part in the management of the bleeding ulcer a new problem has been added to those which the surgeon has to solve during the course of operation. In some cases thorough inspection and palpation of the stomach and duodenum reveals no ulcer and in the absence of any other obvious cause of hæmorrhage the surgeon has to decide whether to operate further or to close the abdomen, as in the four following cases

Case records

Case 1—A woman aged 20 with two years history of epigastric pain coming on an hour after food and relieved by alkalis, was admitted with hæmatemesis pulse-rate 88 blood pressure 125/70 mm Hg and Hb 85% She had another hæmatemesis next day and a blood transfusion of two pints. Four days later bleeding recurred, and her pulse rate was 120 blood pressure 115/60 mm. Hg and Hb 56%

At laparotomy no ulcer was found. Gastrotomy revealed bleeding from multiple small acute erosions In view of the patient's age gastric resection was not considered advisable Two pints of blood was given during the operation. Eight days later the Hb was 56% and the patient was given two pints of blood She was discharged on the eighteenth day after operation.

Case 2—A man aged 53 who had had epigastric pain 1–$1\frac{1}{2}$ hours after food for three weeks had a hæmatemesis. His pulse rate was 70 blood pressure 110/70 mm. Hg and Hb 38% He was given a blood transfusion of three pints Bleeding recurred four days later and he was given three pints of blood and prepared for operation during which two further pints was transfused

At laparotomy no ulcer was found. Partial gastrectomy was done and the patient made an uneventful recovery Dr James McMurray reported on the operation specimen as follows Specimen of lower part of stomach shows acute gastritis, most marked in the prepyloric zone The microscopical preparation shows acute inflammatory change involving mucosa, submucosa, and muscle There is also much fibrosis in the submucosal layer with diffuse chronic inflammatory cell infiltration of mucosa and submucosa. The stomach wall is intensely engorged with blood and is œdematous. The findings indicate acute gastritis superimposed on chronic gastritis.

Case 3—A man aged 77 with no obtainable history was admitted collapsed, pale and dyspnœic with pulse rate 124, blood pressure 115/45 mm Hg, and Hb 26%. Three pints of blood was given. Next day his Hb was 35%, and he was given a blood transfusion of two pints. Two days later a melæna stool was obtained on digital examination of the rectum. Although a further three pints of blood had been given the Hb was 43%. Preoperatively and during operation three more pints of blood was given.

At laparotomy no ulcer was found. Gastrotomy was not done. The patient died three days later. Dr James McMurray reported: "The stomach mucosa shows much autolysis. There are two ulcers on the posterior wall about the mid third of the stomach. One is large (2 × ½ in.) and ellipsoid in outline. The other is small (¼ in.). Both show ulceration down to the muscle layer. A small artery protrudes at the edge of the larger ulcer and is the probable source of bleeding."

Case 4.—A woman, aged 73, known to be hypertensive and subject to epigastric pain after food for two years, had a hæmatemesis. Her pulse rate was 108, blood pressure 104/50 mm Hg, and Hb 50%. She was given a blood transfusion of three pints. Two days later she passed bright blood in a melæna stool. She then had a pulse rate of 102, blood pressure 100/50 mm Hg, and Hb 40%. She was transfused with the cells of four pints of blood.

At laparotomy no ulcer was seen. Partial gastrectomy was done, and the patient recovered. The operative specimen contained a large ulcer, 1½ × ¾ in., down to, but not involving, the muscle layer.

Comments

Case 1 was the only one in which gastrotomy was done. When the lesion was revealed a decision against gastric resection was made in view of the patient's youth. She made a good recovery and required only a further two pints of blood between operation and discharge from hospital. However, these cases are not always so uneventful. Tanner (1950) reported a similar case in a man, aged 26, with hæmorrhage from erosive gastritis, in whom bleeding continued after ligation of the right and left gastric and right and left gastro-epiploic arteries and partial gastrectomy became necessary.

The pathology in the specimen removed from case 2 was identical with that of case 1. In case 2, however, gastrotomy had not been done, partial gastrectomy being undertaken though no ulcer was found. In view of this patient's age I believe that this treatment is correct, and I would have gone on to this operation if gastrotomy had revealed the lesion.

In case 3 gastrotomy would possibly have disclosed the ulcer, because the stomach did not contain blood-clot; but in my opinion the error was in not proceeding to partial gastrectomy notwithstanding the lack of an obvious ulcer. The patient was a very poor surgical risk, and it is doubtful if his life could have been saved; nevertheless he did not receive the benefits of adequate surgery. Case 4 had an identical lesion, again not detectable on inspection and palpation, but with case 3 in mind gastric resection was done, and the result of examination of the specimen amply justified this action.

Discussion

In dealing with patients aged more than 50 and n the absence of any other causal lesion, opinion is ncreasingly in favour of partial gastrectomy if no lcer is found at emergency operation for hæmatemesis r melæna. The surgeon has, however, two other ossible courses of action, gastrotomy or merely to close e abdomen.

The value of gastrotomy is very variable; I have nd it of little value, because it is difficult to examine entire mucous surface of the stomach, especially he presence of blood-clot, which adheres to the stomach l and proves difficult to remove sufficiently thoroughly ve a complete view. Ogilvie et al (1952) write: "Incision of the stomach and duodenal wall and search e the viscus is an unsatisfactory procedure, for it is le to search adequately all the large potential area of bleeding; and the slender prospect of a positive r does not justify the soiling and further loss of blood that method entails."

Closure of the abdomen without further as in case 3, is futile; the patient has been put to t risk of operation but denied the possibility of ben from it. Bleeding ulcers are responsible for ab 90% of massive intestinal hæmorrhages, and in th cases in which operation is considered necessary if lesion is found gastric resection holds the best hope recovery. Ogilvie et al report having done par gastrectomy on seven patients in whom no ulc found; the specimens revealed shallow ulcers or m erosions. Downie (1952) reported six similar Tanner (1950) states:

"If bleeding is of really great severity, and no l is found, then gastrectomy is advisable, for it removes f fifths of the erosive area and partially devascularises remnant."

Ives (1949) asserts that in these circumstances gas-tomy provides no guarantee that an ulcer may not missed, that simply to close the abdomen is a counsel despair, and that a high partial gastrectomy is t correct procedure. My experience confirms the val of these conclusions.

Conclusions

Partial gastrectomy is the operation of choice i emergency laparotomy for hæmatemesis or melæna causal lesion, ulcer or other, is found in a patient more than 50.

Gastrotomy is not very helpful. It is unnec in patients aged more than 50, for whom gastrect should be done. In young patients, as in case 1 repor here, gastrotomy may be of value in deciding ag gastric resection, but note must be taken of the reported by Tanner (1950) and cited above.

CONSULTANT NEUROSURGEON, THE NATIONAL HOSPITAL
NERVOUS DISEASES AND ST GEORGE'S HOSPITAL, LO

SINCE the methonium compounds were introd into anæsthetic practice by Enderby (1950) and Dav (1950) there has been much controversy about th use. It is our view that induced hypotension h not only made possible neurosurgical operations wh could not otherwise be attempted because of obscurati of the operation site by bleeding but also reduces risk of certain intracranial operations.

By the use of hypotensive drugs at operation, cranial pressure can be lowered, thereby diminis the risk of brain damage by herniation through dural opening. A further advantage is gained reducing the operating time, the amount of anæsth required, and blood loss. In the improved operat conditions surgical trauma is lessened. Recovery fr surgery is also quicker.

ough possessing the above mentioned advantages iethonium compounds are lacking in one important ct :– the blood pressure cannot be quickly raised hen lowered again at will The initial fall in blood ure may be greater than that needed in the pre- ary stages of surgery, whilst at a later stage it may impossible to lower the blood pressure quickly emand to the level required by the surgeon at a cular moment for a specific purpose It seems as gh a tolerance to the methonium compounds lops, with the result that, after the initial dose ited injections have less effect The use of procaine e together with hexamethonium bromide (Mason Pelmore 1953, Ascrman 1953) overcomes this ulty to some extent.

hen *Magill et al (1953) reported on the use of the* -acting hypotensive agent Arfonad it seemed able that this drug might produce better control e blood pressure than did the methonium compounds urable reports on the use of arfonad in surgery were published by Nicholson et al (1953) and Sadove . (1953)

perimentally produced acute toxicity varies accord o the route of administration and the species of al used (Randall et al 1949)

March 1953 we obtained a supply of arfonad for Our conclusions concerning its value are based 2 craniotomies done during hypotension induced it. These operations were done for intracranial ders which can be classified as follows

		Anæsthetists				
		S.A	*D.A*	*D.B*	*C.S*	*E.dell*
scular abnormalities						
neurysm	9 cases	6	0	2	0	1
ngioma	8 cases	2	3	1	1	1
ningioma	9 cases	2	6	1	0	0
oma	13 cases	6	5	1	0	1
scellaneous	13 cases	2	10	0	0	1

fonad is a vasodepressor with ganglion blocking and t vasodilator activity Its chemical name is *d* 3, 3 -dibenzyl 2 ketoimidazolido) 1 2 trimethylene phanium *d*-camphor sulfonate

Technique of Administration

ie method of administration we now use is as ws

ter induction with thiopentone used with a relaxant ation is done and an intravenous drip set up The l pressure is recorded The table is now tilted into 30 reverse Trendelenburg position About two minutes the blood pressure is again recorded Blood pressure ation after tilting is of great importance because the n pressure is very variable : and it is a valuable guide o amount of hypotensive drug required. After the scalp been cleaned the arfonad drip is started at first slowly nable the patient s reaction to be observed For the ing stages a systolic pressure of about 80 mm. Hg is idered enough to reduce hæmorrhage

hen the dura has been opened, the pressure is further red (to 60–70 mm. Hg) thereby diminishing intra ial tension and the surgeon s difficulties The blood ure is maintained at this level unless and until a demand ade to decrease it further—e.g., at the moment of excising neurysm

the later stages of operation before the dura is closed blood pressure is returned to near normal or at any rate 00 mm Hg by stopping the infusion and levelling the By so doing the bleeding points are seen and controlled the risk of postoperative blood clot formation is reduced the final stages, but only after replacement of the flap so that extradural bleeding points can be rved and controlled the blood pressure is again lowered bout 80 mm. Hg to prevent blood loss from the skin

naesthesia is maintained with nitrous oxide and gen supplemented by intravenous pethidine. Small es of relaxants are also given if coughing is anticipated

Results

Hæmorrhage

During operation.—In only 2 of the 52 craniotomies was blood loss sufficient to warrant blood transfusion In the 1st case a large suprasellar meningioma was removed which produced *bleeding from the internal* carotid artery The 2nd case was in an infant aged 18 months, subjected to hemispherectomy Of the 17 craniotomies done for cerebrovascular abnormalities 9 were for aneurysm In very few of these cases would radical surgery have been possible without some form of induced hypotension None of these cases required blood transfusion The remaining 8 operations were for angioma all of which would probably have required blood transfusion before the advent of hypotensive techniques as would most of the cases with meningiomas.

Postoperative hæmorrhage.—In 2 cases within forty eight hours of craniotomy the wound had to be reopened for removal of postoperative blood-clot The incidence of this complication is not high Both of these cases occurred before the precaution was observed of raising the blood pressure to normal and arresting all extradural bleeding before replacement of the bone flap In the last 30 cases since this procedure has been adopted as a routine no postoperative clot has been observed

Operative Mortality

Of these 52 patients undergoing major craniotomy 4 died after the operation ; 3 with meningiomata died within forty-eight hours of the operation ; and 1 patient who had an anterior communicating aneurysm and was bleeding at the time of operation died on the tenth postoperative day from surgical occlusion of both anterior *cerebral arteries In all of the 3 fatal cases of meningioma* there was a very large suprasellar tumour extending backwards into the middle fossa and the hypothalamic region 1 of them had been considered inoperable in another hospital and was attempted at the express wish of the relations In each case a major blood vessel (in 2 the internal carotid artery and in 1 the middle cerebral artery) was damaged and had to be clipped These 3 patients were women aged 72, 62 and 55 and poor subjects for such severe operations

In none of these cases was there reason to believe that induced hypotension played any part in the fatal outcome.

Failure to Induce Hypotension

All the patients to whom arfonad was administered responded by a fall in blood pressure In 1 case only was there failure to lower the blood pressure to the level required by the surgeon nevertheless very adequate

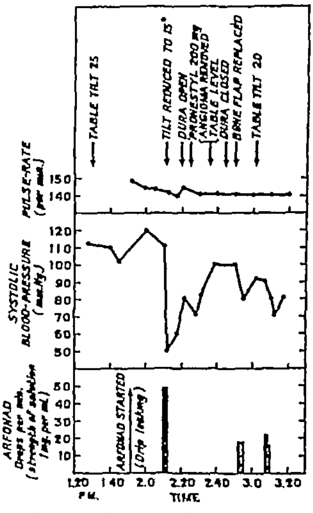

Fig 1—Observations on a child aged 6 ½ years undergoing craniotomy for removal of a posterior parietal angioma. Response was at first unsatisfactory because the drip was "leaking"

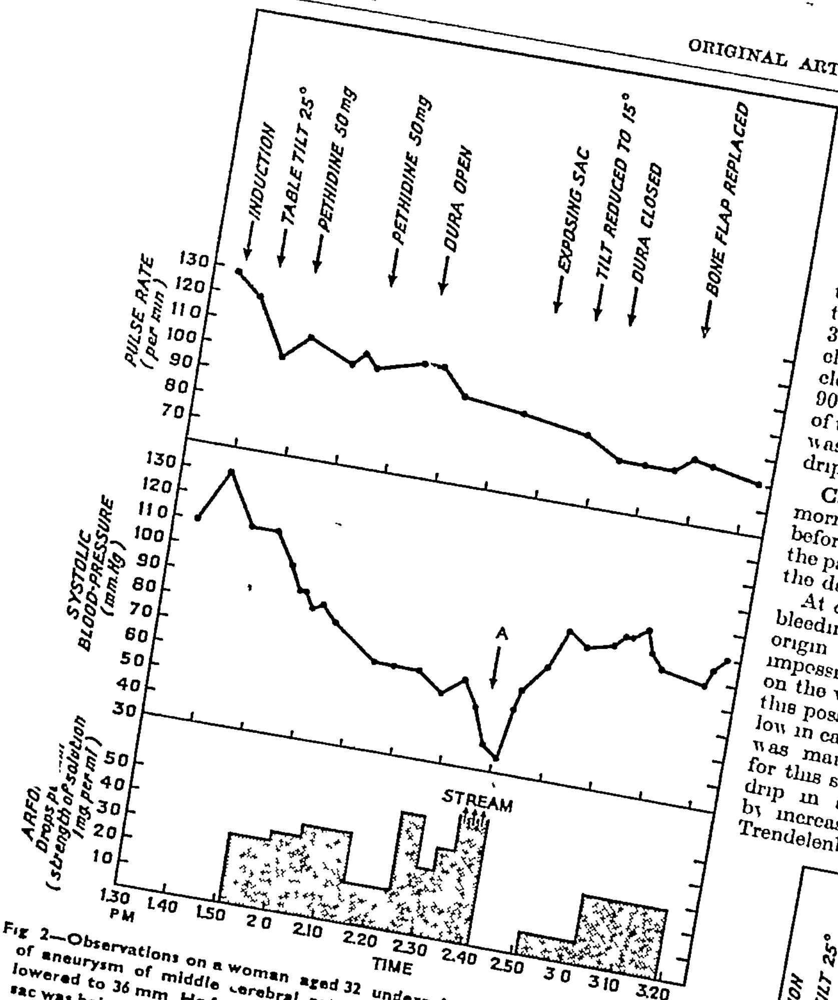

Fig 2—Observations on a woman aged 32 undergoing craniotomy for excision of aneurysm of middle cerebral artery The systolic blood pressure was lowered to 36 mm Hg for two minutes (A) while the neck of the aneurysmal sac was being closed

operating conditions were provided by maintaining the patient's blood pressure at 80 mm Hg

Failure to Maintain Hypotension

After the blood pressure had fallen, the hypotensive state was easily maintained In 2 cases only was it necessary to supplement the arfonad with procaine amide in case 3 to keep the blood-pressure unusually low, and in case 1, a girl aged 6½ years, to lower the pulse rate (see below)

Failure to Restore Blood pressure

Although arfonad is short acting, the blood pressure was seldom restored as soon as the infusion was stopped There was usually a lapse of 1–20 minutes This disadvantage, with 2 exceptions, was overcome by flattening the table In 2 cases 'Methedrine' 5 mg was injected to hasten the return of blood pressure to normal

Illustrative Case-records

Case 1—A girl aged 6½ years had four intracerebral hæmorrhages during the past two years Carotid arteriography showed what proved to be an angioma in the parieto-occipital region At 1 52 P.M the arfonad drip was started (fig 1) After three minutes the systolic blood pressure had risen from 102 mm to 120 mm Hg and the patient was coughing It was then realised that the drip was leaking Once this as rectified at 2 10 P.M a very satisfactory response to the rfonad was obtained

This flexibility of the blood pressure to suit the rgeon's requirements could not have been obtained th the methonium salts, particularly in a child of t g.

Case 2—A woman, aged 32, underwent for excision of an aneurysm of the middl artery After the aneurysmal sac had been its neck was found to be too broad to clos single tantalum clip. It proved necessary del to divide part of the aneurysmal neck and to afterwards with a second clip When the opened quite a severe hæmorrhage took plac this reason, and to facilitate closing the open the sac, the blood pressure was rapidly lower 36 mm Hg for two minutes (A on fig 2) Afte closure was effected, and before the dura mat closed the systolic blood pressure was restor 90 mm Hg to arrest all bleeding points This elev of the systolic blood pressure from 36 mm to 90 m was effected in ten minutes after stopping the a drip and reducing the tilt of the table to about 15

Case 3—A woman, aged 47 was admitted o morning after an intracerebral hæmorrhage th before This was the fourth subarachnoid hæm the past three weeks She was thought to be b the day of operation

At *operation* which was the day of a bleeding site being an intracerebral clot was fo origin of the right middle cerebral arter impossible to dissect this out, so four clips were on the wall of the aneurysm to obliterate it To this possible it was essential to keep the blood pre low in case of hæmorrhage The systolic blood-pre was maintained between 56 mm and 70 mm for this stage of the operation by running the a drip in a continuous stream, and was main by increasing the tilt of the table to 35°–40 Trendelenburg, as well as by giving 500 mg of

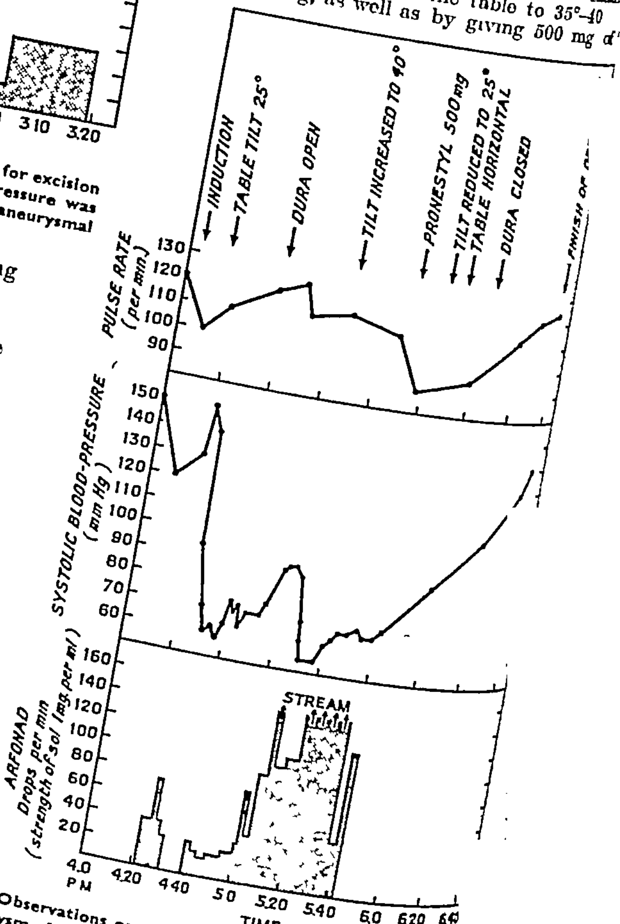

Fig 3—Observations on a woman aged 47 undergoing aneurysm of the middle cerebral artery and removal of The blood pressure was kept low with arfonad supplemen pronestyl while four clips were being placed on the wall aneurysm to obliterate it.

styl to enhance the effect of the arfonad (fig 3) Altogether
patient received 600 mg of arfonad Her systolic blood
sure returned from 70 mm. to 90 mm Hg eighteen
utes after the drip was stopped and was back to her
nal level of 140 mm. by the end of the operation, forty
utes later

his patient was large and healthy and it would have
ved very difficult, if not impossible to produce these
ible results with methonium salts

Conclusions

or operations on the cerebral blood vessels hypo
sion is essential For this purpose arfonad is
erior to the methonium compounds for, being short
ing it gives the anæsthetist greater control of the
d pressure but still reduces the hæmorrhage and
acranial tension to the satisfaction of the surgeon
lowever, it must be emphasised that arfonad is no
wer to the dangers of hypotension, and should only
used in selected cases where the risk is necessary to
uce the greater risk of the operation

Summary

he results are reported of a trial of the hypotensive
nt arfonad in 52 major craniotomies.

he advantages of arfonad over methonium com
nds are discussed

he particular value of arfonad in the vascular surgery
the brain is emphasised Records of 3 cases made
ing operation are illustrated

ll these craniotomies were done by one of us (W McK)
anæsthetists were Dr Donald Blatchley Dr David
rman, Dr Sheila Anderson and Dr Edith de Winter of
neurosurgical unit St. George's Hospital, and Dr Aserman
Dr Cyril Sanger of the National Hospital for Nervous
eases Roche Products Limited kindly supplied the arfonad

RESULTS OF TREATMENT OF INFANTILE CEREBRAL PALSY

EIRENE COLLIS
C.P T M C.S.P., M.A O T., O.N C.
CHARGE OF CEREBRAL PALSY UNIT QUEEN MARY'S HOSPITAL
FOR CHILDREN CARSHALTON

ON an average 130 cases of motor retardation are
rly referred to the cerebral palsy unit of Queen Mary's
spital. The 200 cases discussed here are now under
atment they were referred at ages between 6 months
d 15 years (average age 6½ years)

Treatment was provided for those with motor dys
nction either in the unit or in the child's home. Where
me treatment was instituted the parents were carefully
tructed in the management of their children through
t the day and progress was checked monthly at our
ebral palsy advice clinic held by courtesy of the
thorities at Lambeth Hospital Cases selected for
patient treatment at Queen Mary's Hospital were
ually of normal intelligence but with grossly disabled
otor systems or poor home facilities or both

Treatment is directed towards attainment of normal
ivity including speech; but traditional methods of
ysiotherapy occupational therapy and speech therapy
not employed, and no traditional apparatus drugs
surgery are used Educational facilities are provided
all children over 3 years of age who are inpatients, and these are as nearly as possible those which are provided in ordinary schools The teachers in the cerebral palsy classes are like the rest of the staff, specially trained in the management of motor-deficient children of this type

"Intelligence testing" of any subject must of necessity be *inferior to the test of intelligence afforded by the whole life situation.* The value of formal tests must depend on the skill of the tester this skill becomes of even greater importance where there is defect of the motor apparatus or of sight or hearing Thus one educational psychologist engaged in research into the educability of the cerebral palsied has given up verbal tests and now bases her evaluation of the intelligence quotient on tests of motor competence (Dunsdon 1952) But this is to exchange one component of the thing to be tested for another Certainly intelligence can only be expressed through the motor mechanism, but if this mechanism is defective tests of its competence will not accurately reflect the intelligence using it and moreover the intelligence quotient will shift with changes in motor performance. We base our estimate of intelligence on the response of the child to the life situation itself (Collis 1953)

In the 200 cases here discussed mostly sent to us with a diagnosis of spasticity and mental retardation our findings have been as follows

A group of 26 were found to have unsteadiness of movement (athetosis) and to be of normal intelligence

"Athetosis" is not properly a diagnostic term: originally it was applied to the symptom which Dorland's *Medical Dictionary* describes as "a constant recurring series of slow vermicular movements" Nowadays it is often used as a diagnostic term to cover many different kinds of cases including cases of abnormal movement in mental defectives unmodified reflexes in spastic patients, variable rigidity and even the unsteadiness of ataxia *Here I am using* "athetosis" only to cover that group of cases in which the *sole* neurological abnormality (apart from occasional deafness) is a distortion of normal movement (which may or may not be "vermicular")

Of these 26 14 are now up to normal standard for their ages and are attending ordinary schools; 7 are up to normal standard for their ages in the cerebral palsy class at Queen Mary's Hospital 4 remained at special schools for handicapped children where they were already established; and 1 attends a school for the deaf and is up to normal for his age

Of the remaining 174 cases, 25 were found to be cases of variable rigidity and mental deficiency and these 25 children attend special schools for backward children or remain at home. There were 3 cases of ataxia and one of these attends a school for the deaf where he is up to normal standard while the other 2 are mentally subnormal and are taught at home

The remaining 146 were cases of spasticity and 6 of them are still inpatients in the unit. Of these 6, 2 are of normal intelligence and attend the cerebral palsy class, 2 who are mentally subnormal also attend this class and 2 are not yet of school age Among the outpatients 8 attend *normal schools,* and 132 (including 10 hemi plegics) attend special schools or have home tuition; all these are mentally subnormal in greater or lesser degree

This gives an estimate of normal intelligence in only 20% of cases referred and this 20% includes all those with athetosis (26) 13 with spasticity and 1 with ataxia Of the remainder (mentally subnormal) 67% had spasticity 12% had variable rigidity and 1% had ataxia

In cases of infantile cerebral palsy a classical clinical picture is expected to develop but our 12 year study has shown that the appearance or non appearance of classical neurological signs deformity and motor dysfunction largely depends upon the physical handling the children receive in the early stages. It has been found that where intelligence is normal the young child can learn to use his defective motor system in a *normal manner* and deformity does not develop It has also been found that even where gross dysfunction and deformity are already established, the condition of affected children can be greatly ameliorated, and those of normal intelligence become able to express their mental processes intelligibly in movement, including speech Those of subnormal intelligence, though their achievements are limited by their mental incapacity, become efficient in greater or lesser degree and often cease to be a grave burden to their families

I am grateful to Dr C D S Agassiz for permission to publish data obtained at his hospital, Queen Mary's Hospital for Children

EFFECTS OF INHALATION OF SULPHUR DIOXIDE BY MAN

Mary O Amdur
Ph D Cornell

Walter W Melvin, jun
M D Colorado

Philip Drinker
Chem Eng, Sc D (Hon) Princeton

From the Department of Industrial Hygiene, Harvard University School of Public Health, Boston 15, Massachusetts

In the London fog of December, 1952, the densest concentrations of sulphur dioxide were 1 339 p p m and of smoke 4 46 mg per c m on Dec 7 and 8, when the fog was at its worst (Scott 1953, Logan 1953) Both values are much greater than normal for that season of the year In this connection the results of our laboratory studies of the respiratory response of man to low concentrations of sulphur dioxide are of interest

METHODS

Concentrations of sulphur dioxide were established in a 2 c ft 'Lucite' chamber by metering in diluted sulphur dioxide (1% in air) from a steel cylinder The sulphur dioxide joined the main air-stream (5 c ft a minute) before entering the chamber so that mixing was achieved The concentrations of sulphur dioxide in the chamber were measured by the conductivity method of Thomas and Abersold (1929)

The subjects of the experiment were at breathed through a face-mask A slide valve hid their view enabled the mask to be connected chamber without their knowing it The vol expired air was measured in a spirometer, whic read every minute The respiratory rate and p were obtained with a pneumotachograph (Silverman Whittenberger 1949), a device for instantaneous recor of air flow during breathing It consists of a fine 'M wire screen mounted in a face mask The screen mea the movement of air by measuring its velocity volume through the screen by pressure loss or resist of the screen, which bears a linear relation to the The pressure corresponding to the flow is measured a thin membrane whose movement is transmitted electrical recording device From the direct trac whole breathing pattern, inspiratory and flow-rates, and other breathing characteristics obtained

RESULTS

The ability to detect sulphur dioxide varied from person to person Concentrations of 1-2 p were not usually detected At 5 p p m most complained of a slight feeling of dryness in the and upper respiratory passages, but they could actually "smell" it One person found 5 p p m objectionable that the exposure was stopped after minutes, whereas others barely noticed it. Pe exposed to 6–8 p p m definitely detected dioxide in the air but said they became accusto it as the exposure continued

Fourteen normal people exposed to sulphur 1–8 p p m showed changes in respiration and p Tidal volume decreased, respiratory rate incr minute volume remained unchanged, and puls increased

Fig 1 shows the average values of tidal respiration-rate, and pulse rate for five people ex for ten minutes to 5 p p m The same pattern of c was followed by each person Tidal volume fell sh at first and then levelled off at about 25% below control value Respiration increased by three or breaths a minute, and pulse rate by eight or nine the control levels when exposure ceased These values all return

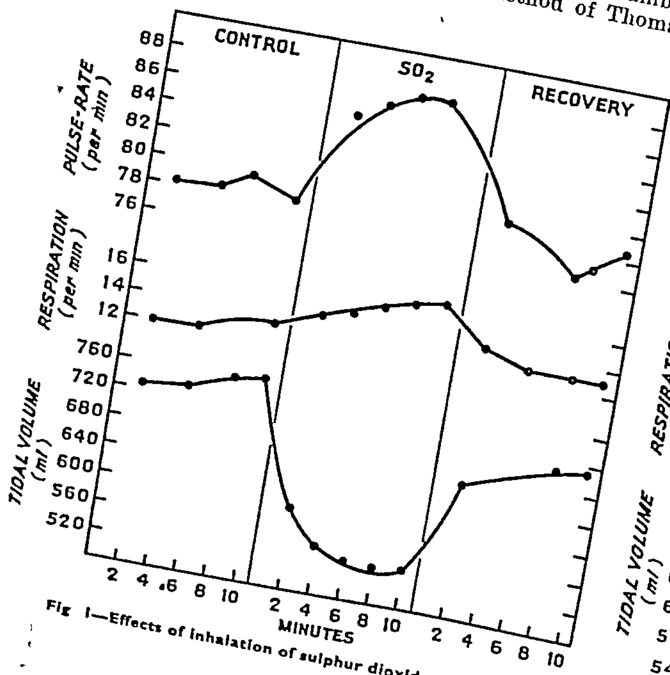

Fig 1—Effects of inhalation of sulphur dioxide 5 p p m

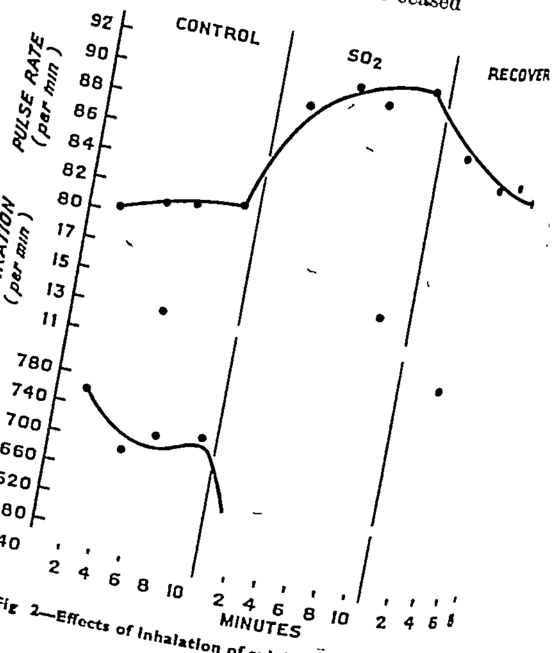

Fig 2—Effects of inhalation of sulphur dioxide 1 p.p.m.

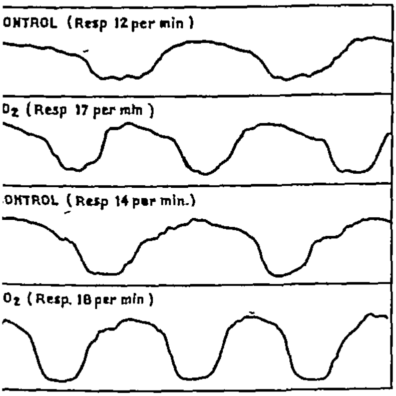
2 presents the average of four people exposed to m It is at once plain that the pattern of changes he same as that for 5 p p m The tidal volume ased during the first two minutes' exposure to about below the control levels During the remainder of posure period however it increased again to about below control values

3 shows respiratory tracings obtained from two e one exposed to 2 p p m and the other to 1 p p m. ncreased respiratory rate is indicated The area the curves may be taken as an indication of tidal ne although this method was not used to measure it. e people so far discussed had no routine exposure lphur dioxide To determine whether the same s would be obtained from people regularly breathing spheres containing sulphur dioxide two men from dustrial plant were exposed to 5 p p m These men d tending boilers in which an oil of high sulphur nt was burned. The concentrations of sulphur le in their working environment often exceed the



—Pneumotachograph tracings. Upper portion of tracing is expiration, lower portion is inspiration.

ican maximal allowable concentration of 10 p p m ded for eight hour exposures (*Archives of Industrial ene and Occupational Medicine* 1952) Fig 4 shows esults of the tests on these two men Apart from a ble transitory increase in respiration the changes ved in the other people were not shown by these

This seems to show that respiratory and cardiac nses to sulphur dioxide were less in them than in le who had not previously been exposed to it gard (1923) states that the apparent tolerance of men is due to chronic inflammation of the upper assages producing a tenacious mucus which acts as otective coating In his opinion deadening of the k has removed one measure of protection

DISCUSSION

lphur dioxide in concentrations as low as 1 p p m produce shallow rapid respiration and increased e-rate. We have previously shown (Amdur et al) that comparable respiratory changes are produced sulphuric-acid mist in concentrations as low as mg per c m Although we have seen no report of entrations of sulphuric-acid mist during the peak e London fog this substance is a known constituent ch fogs

l the subjects of our experiments were healthy men 28–58 No persons with pre-existing respiratory or iac disease were studied.

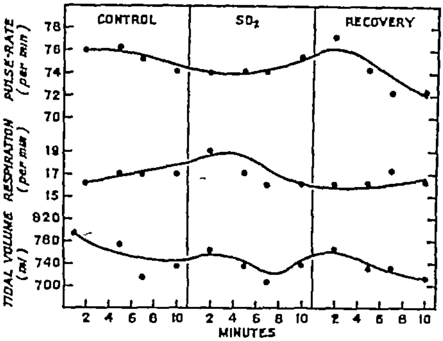


Fig 4—Effects of inhalation of sulphur dioxide 5 p.p.m by workmen (A and B) regularly exposed to high concentrations of this gas.

SUMMARY

Normal people inhaled sulphur dioxide 1–8 p p.m through a face mask for ten minute periods

In all of them shallower and more rapid respiration and increased pulse rate were observed during exposure Similar but slighter changes were observed with sulphur dioxide 1 p p m

Men who worked daily in atmospheres containing sulphur dioxide 10 or more p p m showed no changes when exposed to 5 p p m

POLYCYTHÆMIA WITH FIBROIDS

A P Thomson
M.C M.D Birm., F R C.P
PROFESSOR OF THERAPEUTICS IN THE UNIVERSITY OF BIRMINGHAM

F G W Marson
M.D Birm. M R C P
LECTURER IN MEDICINE, UNIVERSITY OF LEEDS; FORMERLY SENIOR MEDICAL REGISTRAR, GENERAL HOSPITAL, BIRMINGHAM

The following case is recorded because manifest and serious polycythæmia disappeared immediately after removal of large uterine fibroids by hysterectomy together with bilateral salpingo-oophorectomy

CASE RECORD

A married woman aged 48 was referred to the outpatient department on Feb 14 1951 with two years history of attacks of transient blurring of vision soreness of the eyes and muscular fatigue. She had always been of high colour but this had noticeably increased during the previous two years She denied headache or dyspnœa No history of drug treatment or exposure to chemical agents was obtained. Menstruation had been irregular for two years with scanty loss, and at no time had she had menorrhagia. Her previous health had been good, and there was no relevant family history

On examination she was small (weight 100 lb) with congested face and bloodshot eyes Her whole skin was deep reddish blue Her retinæ were deeply coloured and the retinal veins engorged. Her abdomen contained a large mass rising from the pelvis and extending upwards to the umbilicus A further mass, freely mobile and as big as an orange, was present in the left hypochondrium There was no enlargement of the liver or of the spleen The cardiovascular system appeared normal, the blood pressure was 160/90 mm Hg No abnormal signs were found in the respiratory and central nervous systems There was no finger clubbing The urine contained neither albumin nor sugar

Investigations—A blood count showed red cells 7,280,000 per c mm, Hb 148%, colour-index 1 0, white cells 5800 per c mm (polymorphs 78 5%, eosinophils 1 5% lymphocytes 15%, monocytes 5%), platelets 125,000 per c mm, packed cell volume 72 c cm, mean corpuscular volume 88 c μ, mean corpuscular hæmoglobin concentration 30%, bleeding time 1½ minutes, clotting time, initial 6½ minutes, final 7 minutes, prothrombin time 18 5 sec with control 25 sec The plasma volume was 2040 ml (Evans blue method)—i e, the blood volume was 7286 c cm Radiography of the chest showed lungs striated, but no other chest abnormality" No evidence of arteriovenous aneurysm was found on screening the chest The long bones were radiologically normal These results excluded polycythæmia vera but did not reveal any of the recognised causes of secondary polycythæmia

Operation—Laparotomy was done by Prof Hugh C McLaren on March 27, 1951, and the abdominal masses were found to be multiple fibroids, one of which was pedunculated and freely mobile Total hysterectomy, bilateral salpingo oöphorectomy, and appendicectomy were done without untoward incident or excessive hæmorrhage The spleen was not enlarged

Postoperatively the patient's recovery was uneventful Pathological examination confirmed the nature of the tumours

Date	Red cells per c mm	Hb %	Colour index	White cells per c mm	Platelets per c.mm.

Jan 21 1953	4,750,000	92	0 97	7700	238,000

* This count was made at All Saints Hospital, Bromsgrove, W

A week after operation the hæmoglobin value had fall 114%, and it continued to fall to normal levels blood counts have shown no recurrence of poly during the last twenty-two months (see table) The symptoms have been completely relieved.

COMMENTS

We have been unable to find any published rep an association of secondary polycythæmia with fibroids, nor any record of its complete relief by removal of the tumours We can suggest no explanation of this phenomenon

Medical Societies

ASSOCIATION OF CLINICAL PATHOLOGISTS

THIS society met in London on Oct 1–3 Dr E N DAVEY (Gloucester) was appointed president elect The chairmen at the various sessions were Prof Matthew Stewart, Colonel L R S Macfarlane, Prof R Knox, Dr J V Dacie, Prof J Heimbeck (Oslo), Prof R J V Pulvertaft, Mr C P Stewart, D SC, and Dr H B May

Nævi and Malignant Melanomas

SOPHIE SPITZ and ARTHUR C ALLEN (New York) discussed the clinicopathological correlation of nævi and malignant melanomas Their many beautiful illustrations were chosen to show how difficult it may be to confirm or exclude malignancy in pigmented tumours After presenting their classification and describing the various clinical and histological types, they reviewed the evidence in support of humoral activation and referred to the receptivity of the newborn to secondaries transmitted from the mother By contrast only two instances of primary melanocarcinoma had been recorded in infants, and in neither case was the evidence satisfactory

GEORGIANA BONSER (Leeds), who opened the discussion, referred to the part played by trauma in causing malignant transformation Dr ALLEN believed that it was very commonly held that trauma of a nævus was fraught with danger, but that in practice it was the junctional nævi which were liable to undergo malignant change and these were the ones most commonly found on many of the areas liable to trauma such as the sole of the foot Perhaps therefore the so called vulnerable areas were vulnerable because junctional nævi were so commonly found there

Professor STEWART referred to an instance in which the malignant cells had evidently been kept in subjection for a long time A large necrotic mass had been found in the sacrum but at necropsy metastatic melanocarcinoma was found in the liver It transpired that an eye had been removed some years earlier on account of a malignant melanoma the pelvic mass was deemed to be a greatly delayed secondary while the liver deposits were assumed to be tertiaries

Malignant Hypertension

G J CUNNINGHAM (St Bartholomew's Hospital) described two cases of malignant hypertension with kidneys which were partly smooth and partly granular The first was a 60 year old with mild hypertension whose illness suddenly became more acute and serious 3 years later She presented on second occasion with dyspnœa, vomiting, and bot and visual disturbances The blood pressure was mm Hg and the blood urea 352 mg per 100 ml De followed The second patient was a man, aged 30 w intermittent claudication 5 years later he suffered paroxysmal dyspnœa with a blood pressure of 270/1 Hg He died soon afterwards in coma Each case w to have aberrant renal arteries, one of which had le obstructed by a thrombus It was a matter of interest the parts of the kidneys supplied by the thrombosed showed mild hypertensive arteriosclerosis—the smooth —while the remainder of the kidneys supplied by the p vessels were grossly diseased, containing numerous an fibrinoid degeneration in both glomeruli and arterioles aberrant vessels were normal in appearance but the bosed vessels revealed underlying atheroma of a degree sufficient to produce a measure of obstruction and to the development of severe lesions in those parts organ Because of the resemblance of the kidneys to produced experimentally by Byrom and Wilson in Dr Cunningham referred to his cases as "a nat occurring experiment"

Colitis Cystica Profunda

H B GOODALL (Dundee) described two examples of c cystica profunda The first patient had suffered from cytic anæmia and mucous diarrhœa followed by pe obstruction the second from chronic ulcerative colitis severe bleeding In neither case were pathogenic org found The peculiar breaches in the muscularis m secondary to abscess formation, were believed to be of cance and the probable cause of the ingrowing mucus-sec epithelium and the consequent formation of cysts

Epiloia

L CROME (Fountain Hospital) dealt with the st features of epiloia, and indicated their relative fre Incomplete forms of the disease should be sought parti among the relatives of patients with the fully disease Dr Crome described in his series two fibroelastosis of the heart and referred to two other examples

Malignant Disease of Bone

Professor PULVERTAFT and J G HUMBLE (W Hospital) demonstrated a film prepared by phase- microscopy which included examples of myelomatos other malignant conditions of bone

Epidemic Hæmorrhagic Fever

Colonel **Hugh R. Gilmore** (Washington) described the nical and pathological features of epidemic hæmorrhagic or sometimes called Korean fever Although fighting gan in Korea in June 1950 it was not till the summer of 51 that the disease was recognised in United Nations troops, d it reappeared in 1952. It has affected only troops in the gion of the 38th parallel and in rural areas it has not been ted in Southern Korea. Cases have first appeared in May th the advent of the light spring rains and have reached peak in June The incidence curve then falls after the mmer rains and rises to a second and higher peak with the season in October The incidence of the disease in a litary unit is not heavy for only a few individuals in a mpany may be affected and they may all be in the same uad There has been no evidence of spread from person to rson or through water or food but it has been noted that ldiers may contract the disease after being confined for a ile to certain areas, suggesting therefore an insect vector ited States workers consider a trombiculid mite (chigger) be the responsible vector and these are known to be tributed in highly localised foci at a time when the disease urs and to have a limited range of movement Japanese d Russian workers however earlier believed that the ease was conveyed by *Laelaps jettmari* a mite found on the mmon field mouse. Although there would appear to be re support for the former view the disease has not so far en transmitted to animals, and both the causative agent and means of transmission remain unproven Second attacks ve not occurred.

The onset is acute with a febrile stage accompanied by dache back pain and anorexia Nausea and vomiting are mmon after the first 24–48 hours. The patient may complain photophobia blurring of the vision, and orbital pains, ile a scarlatiniform rash of the face and neck earlier on in disease is typical together with infection of the conjunc- a and pharynx Albuminuria appears about the 3rd or 4th y together with casts and often erythrocytes One should itate to make the diagnosis in the absence of albuminuria ter 3–5 days the fever subsides and convalescence begins the more serious cases, however petechial hæmorrhages pear about the 4th day on the palate and shortly afterwards ng the axillary folds and the lateral chest wall and neck od may appear in the urine stool or vomitus Subcon ctival bleeding was common in the outbreak of 1951 but s frequent in 1952 During the hæmorrhagic phase there y be repeated episodes of shock during which the patient y die The shock is accompanied by oliguria, azotæmia, d persistent vomiting but if recovery occurs a period of uresis follows. The mortality rate was 8% in 1951 and about in 1952

Leucopenia is usual in the early stage but later there is cocytosis with an increase of immature granulocytes. out 90% of patients show an increased capillary fragility the Rumpel Leede test while moderate thrombocytopenia urs in about 75% of the patients The shock which appears be responsible for about two thirds of the deaths is umed to be due to loss of serum through damaged illaries Deaths in the later phases are associated with hydration fluid and electrolyte imbalances and renal lure Necropsy findings include hæmorrhages in the kidneys, ht auricle anterior pituitary and occasionally the adrenal cal hæmorrhages have been seen in the meninges and in Focal myocarditis and mild diffuse interstitial pancrea is have been observed in some cases while there may be rosis of the anterior lobe of the pituitary extending into infundibulum of the pyramids of the kidney of the renals and occasionally of the islands of Langerhans The ions suggest the presence of an agent which causes capillary mage and either directly or on account of tissue anoxia, lular necrosis There is no swelling of the capillary endo lium as in typhus. No treatment has been found to be of all other than absolute rest Evacuation by helicopter her than by ambulance is believed to have saved lives. te-repellants are now freely and successfully used in the ected areas.

Intestinal Spirochætosis

A. G. Sierra (Eastbourne) described instances of intestinal rochætosis associated with persistent relapsing diarrhœa.

Staphylococcal Coagulase

E. S. Duthie (Southampton) spoke on the mode of action staphylococcal coagulase which is of two sorts—the bound and the free The former acts directly on the fibrinogen of certain animals and is the one concerned in the slide test commonly employed; the latter which is responsible for the reaction in the tube test is liberated in the culture medium and clots any fibrinogen provided that an activator is present. Bound coagulase is liberated in autolysis and its presence can be shown by an antibody inhibition test. Reference was made to the value of these separate forms of coagulase in the preparation of vaccines

Laboratory Investigation of Poliomyelitis

G. L. Le Bouvier (Colindale) described recent developments in the laboratory investigation of poliomyelitis, mentioning in particular the value of tissue culture in the identification of the strains of the virus. Type 1 was first identified in this country in London in June 1946 type 2 in Stowmarket in August 1951 and type 3 in Cardiff in December 1951 All three types occur from time to time. The complement fixation test is held to be of little worth in the diagnosis of the disease, but it is of value in epidemiological studies.

Hæmophilia and Christmas Disease

J. R. O'Brien (Plymouth) discussed the differential diagnosis of hæmophilia and Christmas disease for several families credited with having had the former are now known to have had the latter Patients with Christmas disease have a long, although sometimes a normal, clotting time an abnormal prothrombin consumption, and a delay in thrombin generation In the laboratory the defect can be made good by normal plasma The thromboplastin generation test is used to decide whether the fault lies with the serum factors amongst which is the Christmas factor or the alumina-treated plasma fraction containing the antihæmophilic globulin Blood used in transfusing these patients must therefore contain the Christmas factor the anti hæmophilic factor being unnecessary In a patient studied over a period of 5 months it was noted that the clotting and prothrombin-consumption times were readily restored to normal with blood and plasma transfusion but that 4 pints was usually needed to restore temporarily the thromboplastin generation test to normal and bring about a cessation of the bleeding

Erythræmic Myelosis

G. Discombe and **K. H. Nickol** (Central Middlesex Hospital) described a case of erythroleukæmia in which the prolongation of life by means of transfusion had made it possible to study the pathological process at a later stage of the disease The patient a man aged 72 eventually developed an acute granulocytic leukæmia and died of cerebral hæmorrhage These workers suggest that as nothing is known as to their pathogenesis the so called erythræmic myelosis or Di Guglielmo's disease and acute leukæmia with erythroblastic onset should be grouped together

Sickle cell Trait

H. Lehmann (St Bartholomew's Hospital) dealt with the distribution of the sickle-cell trait In negroid Africa the highest incidences are found in the north and east falling somewhat towards the west and diminishing towards the south, so that in South Africa it is virtually absent In Uganda it is about 20% in the Nilotic-speaking tribes but almost nil in those speaking a language related to Hamitic. In the Bantus the incidence of the trait varies in inverse proportion to the degree to which they were in contact with the recent Hamitic invaders. Thus it might seem that the trait came from Asia In Europe some sickle-cell trait carriers are found in Italy and a few isolated pockets with high incidence exist in Greece Wherever the sickle-cell trait is frequent there is malaria, a low social status and close inbreeding

Diagnosis of Myelomatosis

J. G. Humble and **V. F. Maclagan** (Westminster Hospital) discussed sternal marrow findings and flocculation tests in the diagnosis of myelomatosis.

Iron containing Granules in Erythrocytes

A. S. Douglas and **J. V. Dacie** (Postgraduate Medical School of London) described the incidence and significance of iron-containing granules in human erythrocytes These were found to be present in reticulocytes but rarely in adult erythrocytes except following splenectomy They believed that the spleen might be responsible for the assimilation of iron in the synthesis of the hæm molecule

Tests in Burned Patients

S SEVITT (Birmingham) had made use of corticotrophin (A C T H) or adrenaline to determine whether acute adreno cortical failure in burned patients was still present after the eosinophils had returned to normal Of 14 patients tested with corticotrophin 12 gave normal eosinophil depression curves indicating normal stimulable reserves of the adrenal cortex The remaining 2 failed to produce eosinopenia The 1st ultimately died, but a few days after the test spontaneous eosinopenia developed, indicating that if failure had occurred earlier it was of short duration The 2nd patient continued to produce abnormal curves until the 16th day when the test became normal In 9 of the 12 patients tested with adrenaline normal curves were found Abnormal results were found in 2 children who had become confused and irrational Since adrenaline produces eosinopenia indirectly, probably via the hypothalamus, its lack of eosinophilic effect in a patient reacting normally to corticotrophin is probably due to pituitary or hypothalamic disturbance

Test for Tuberculous Meningitis

The value of a test for early tuberculous meningitis based on the passage of bromide from the blood to the cerebrospinal fluid was reported by HONOR SMITH and G HUNTER (Oxford) The transference of this substance appears to be greatly facilitated in tuberculous meningitis when compared with comparable forms of meningeal inflammation

Demonstrations and Address

The next session was devoted to demonstrations and to r R G MACFARLANE's film on sternal puncture There ter Prof DOROTHY RUSSELL delivered a presidential address rinted on p 771)

Tests of Pituitary Function

J HARKNESS and C DONOVAN (Portsmouth) had confirmed the findings of Stewart, Horn, and Robson (1953) in which it was shown that corticotrophin causes an increase in the plasma total ascorbic acid together with an increased proportion of ‘ reduced ascorbic acid,” whereas cortisone causes no change in the total level although there is an increase of ‘reduced ascorbic acid ” They now described a test of pituitary function based on the ascorbic acid levels after an injection of corticotrophin The degree of response in some psychotics was found to be lower than in normal controls Changes similar to those produced by corticotrophin were noted after electroconvulsive therapy, emotional stress, oral sodium salicylate, or phenyl butazone

Steroids and Water Metabolism

M LAMOTTE and L JUSTIN BESANÇON (Paris), whose paper was presented by J J BERNIER, referred to the influence of steroids on water metabolism Œstradiol was effective in increasing the total water content of the body but glomerular filtration remained practically unaltered although the calculated renal plasma flow was slightly lessened Diuresis provoked by water consumption was not modified, but when brought on by saline it was considerably lessened Sodium chloride was not eliminated, the arrest of the sodium being the reason for this Testosterone, on the other hand, induced an increase of weight without any increase of either total or extracellular water in other words the increase of weight was due to an increase in body tissue The renal plasma flow however, was increased as was also the diuresis induced by water or saline The elimination of sodium was only impaired if the kidneys had been previously damaged Cortisone caused a marked retention of water and sodium yet increased both glomerular filtration and the renal plasma flow Notwithstanding this diuresis induced by the ingestion of water was increased In these studies the total water-content was estimated by the antipyrin method, and the extracellular water by the mannitol technique

Postoperative Retention of Salt and Water

A V G LEWIS and L P LE QUESNE (Middlesex Hospital) ealt with the problem of the postoperative retention of salt nd water For 24–48 hours after operation (the observations ere made on gastrectomy patients) there is a diminished cretion of water the result of release of antidiuretic hor one This is due to the emotional disturbance associated th the operation and is probably accentuated by morphine and anæsthesia Sodium retention occurs in two phases, separated by an increased sodium excretion the fir the day of operation, is probably mainly due to hæmody factors, the second, usually beginning on the 3rd day, be considerably reduced by ensuring a reasonable potas intake throughout In some cases, particularly wh potassium was given, continuous postoperative sodium water retention could be observed In the discussion w followed reference was made to the value of weighing for the rapid assessment of sodium and water retenti

Fallacies of the Test-meal

F AVERY JONES (Central Middlesex Hospital) refer the fallacies of the test meal The shaded area on many meal charts corresponds to the findings in 80% of Be and Ryle's series of healthy subjects The remaining although they show less or more acid than the majority, nevertheless in perfect health A high or low reading the should not be taken to imply an irregularity of gastric fun Follow up studies on patients with high readings have shown any correlation with dyspepsia, unless there wa increased volume of secretion A high acid curve ma due to rapid emptying or to hypersecretion Achlorhydria clinical practice implies a gastric juice with pH greater 3 5, but at this level there is still a little acid present Pa with histamine fast achlorhydria may be studied furth 24 hour pH curves, those with primary anæmias give a of 4 5 or higher, whereas those with ulcer dyspepsia have acid for many hours throughout the day The main ind for a test-meal is in those patients with vague sym referable to the upper abdomen in whom radiological have been negative In such cases the test might be h in revealing the presence of carcinoma by gross blood ing and an increased difference between the free acidity Acid is found in at least a third of patients carcinoma of the stomach. Dr AVERY JONES always it valuable to know if the blood reported as present fact gross bloodstaining or merely positive for blood chemical tests He believed that very little was to be from the routine use of test meals in cases of peptic ulc

In the discussion which followed he said that he pref the gruel test meal to the alcohol meal because the produced a more physiological form of distension o viscus A nasal tube was easier for the patient and certainly to be preferred when a 24 hour test was indi The tubeless test meal was probably adequate for the gation of cases of pernicious anæmia He agreed that management of the patient during the test should be hands of an experienced and competent sister familiar all the pitfalls in the technique, and that failure to ob this precaution was liable to produce unsatisfactory misleading results

Tests of Glomerular-filtration Rate

J E CRAIK and A P KENNY (Glasgow) reported a series of 63 patients in whom the thiosulphate and clearance tests had been compared The estimation of pl thiosulphate was found to be unsatisfactory, and mor it appeared that thiosulphate was actively excreted by tubules the excretion becoming maximal at p thiosulphate concentrations of 16 mg per 100 ml. estimation of thiosulphate clearance was inadequate measure of glomerular filtration rate These workers adv evidence that in myxœdema tubular reabsorption thiosulphate is inhibited

Estimation of Serum-cholinesterase

B W MEADE (Westminster Hospital) reported that colorimetric determination of serum cholinesterase was s factory for routine use, but that the test had proved of l value in the diagnosis of thyrotoxicosis

Liver-function Tests in Rheumatoid Arthri

P W DARBY (Westminster Hospital) described his in 50 cases of rheumatoid arthritis in which a battery o function tests had been carried out While positive flocc tests which he obtained represented changes in the s proteins which might or might not be due to liver disea results with Mateer's bromsulphthalein test and the estim of urine coproporphyrin as recommended by Sch showed that in rheumatoid arthritis a degree of liver d exists which is significantly greater than that with ill health from other causes

Reviews of Books

posal of the Dead

C J Polson M D Birm F.R.C.P professor of forensic medicine; R P Brittain M.A B SC M B LL.B Glasg senior lecturer in forensic medicine; T K Marshall, M B Leeds, lecturer in forensic medicine University of Leeds. London English Universities Press 1953 Pp 300 21s

To collect in one volume the more important material ncerning the disposal of the dead was a good idea d this book after a historical introduction deals with diate disposal (including death certification and gistration), cremation burial (including funeral rites) humation embalming and funeral direction Admit lly, if the object were an exact and comprehensive position of the law and practice many of these subjects ould require a textbook to themselves; and though e book is full of useful and curious information it ffers in places from lack of detail

Thus the 4 pages on anatomical dissection would be the tter for expansion The distinction is not clearly drawn tween the main sources of supply to schools of anatomy i.e the unclaimed bodies of persons dying in welfare stitutions, and bodies made available by voluntary bequests ere is also confusion between the Anatomy Act which an Act for Regulating Schools of Anatomy and o practice of post-mortem examinations In references sections of the Anatomy Act the number of the 1940 der extending the period before interment is misquoted d a similar Order for Scotland, which preceded that for gland and Wales by twenty four years is not mentioned d a reference to the forms required at Leeds, little is which would help funeral directors to deal with the al procedure in cases where a voluntary bequest has been o for anatomical dissection The chapters on cremation l embalming are excellent but that on international ansport of the dead refers neither to the sailor s dislike of rrying bodies on a ship nor to the International Agreement ncerning the Transport of Bodies signed in Berlin in 1937 though this has only been ratified by some dozen untries

For such reasons it would perhaps be well to make the xt edition rather larger But in its present form it ls the greater part of a considerable gap The medical ader will find much to inform him and so of course ll the funeral director, for whom the book is primarily tended

he Surgery of Infancy and Childhood

Its principles and techniques Robert E Gross, M D D SC., William E Ladd professor of children s surgery Harvard Medical School. Philadelphia and London W B Saunders. 1953 Pp 1000 80s

This is the record of Professor Gross s long experience he subject covered is pædiatric surgery—after the ortho-ædic surgeons have claimed the fractures and deformities, e plastic surgeons the cleft lips and palates the nose and hroat surgeons the glands of the neck and the disorders f the nose and throat and the neurosurgeons the ills of heir chosen domain Professor Gross is fortunate in etaining the chest and urological surgery which in this ountry would also probably go elsewhere However here is more of the child left than one might suppose nd in each of the 61 chapters of this book there is a orking plan for the diagnosis, treatment, operation and ftercare of a disability The author has himself tried nd proved the steps recommended and the young urgeon who has had little experience of children s urgery could follow the instructions and never go far rong. It is a book which could never be written by young man: not a word is based on hearsay or heorising

Certain differences in approach and technique from ours re inevitable Few anæsthetists in large centres in England, or instance would nowadays agree that the open mask drop method is the anæsthesia of choice for these cases though hey would have done so ten years ago Drainage is advocated or appendicitis with peritonitis more often than would be the case here Infants with hypertrophic pyloric stenosis are given 10% glucose intravenously 10 ml per lb per day and subcutaneous saline 15 ml per lb per day The 10% glucose is hypertonic and makes adults very thirsty and the amount of subcutaneous saline administered is equivalent to giving 10½ st man 2250 ml of fluid subcutaneously every [illegible] four hours—an experience from which even the stout [illegible] would shrink.

Discussing duodenal atresia Professor Gross [illegible] of careful assessment of the child s mental state [illegible] made since many children with duodenal a[illegible] mongols—the implication being apparently t[illegible] thought to be mongols should be allowed to [illegible] seems dangerous reasoning But if his book [illegible] evokes opposite opinions it is nevertheless [illegible] deserves to find an honoured place in all pæd[illegible] centres.

Stress and Disease

Harold G Wolff M.D professor of medicine [illegible] logy) Cornell University Springfield Ill Ch[illegible] Thomas. Oxford Blackwell Scientific Publ[illegible] 1953 Pp 199 40s

This monograph in the American Lectures in [illegible] logy series brings together in a small volume [illegible] original work which Professor Wolff and his col[illegible] have already published It offers a concise re[illegible] some of man s reactions to danger and his a[illegible] responses which Dr Wolff has done so much to [illegible] by controlled experiment Many of his results a[illegible] known, for he is a pioneer of the scientific inves[illegible] of the effects of emotion on the human body To [illegible] the concepts expounded may seem too wide and comprehensive, the arguments uncritical; to [illegible] the evidence will be convincing But none can fail [illegible] fascinated by the skill and brilliance of the w[illegible] Broad principles are related to particular exampl[illegible] demonstrable changes in the subject These are [illegible] based on animal studies but on the results of [illegible] stimuli to the skin the stomach, the colon, the [illegible] or other organs of the human being Many [illegible] conclusions seem common-sense comments on [illegible] observations but it is rare to find them so [illegible] expounded Man s reaction to man may be [illegible] as important as his reaction to a microbe and the [illegible] of a danger may call forth responses little di[illegible] from the assault itself Professor Wolff pr[illegible] evidence that man must pay some price for the [illegible] which he lives—and that some of the price of adap[illegible] and reaction may be pain and disease In the cont[illegible] and well adjusted subject the response to an [illegible] or a stress may be transient and harmless but [illegible] conditions of anxiety or resentment, caused by a [illegible] a drug or the mere effort of coping with day [illegible] burdens this same person may react quite diffe[illegible] It is therefore in fostering the adaptive-pro[illegible] response and in changing the way in which a par[illegible] subject perceives a stress that the physician m[illegible] able to do most good; and Dr Wolff believes that [illegible] 730 subjects two out of three were constructively a[illegible] during a three year period of study The main ther[illegible] peutic aim was to produce tranquillity and freedom fro[illegible] sustained hostility and resentment

Founders of Neurology

Editor: Webb Haymaker, M.D., chief neuropathology section Armed Forces Institute of Pathology Washington D C., with the biographical and editorial assistance of Karl A Baer. Springfield, Ill Charles C Thomas. Oxford: Blackwell Scientific Publications 1953 Pp 47[illegible] 75s 6d

If the purpose of biography is to inspire by examp[illegible] Dr Webb Haymaker and his associates may well [illegible] content with this interesting illustrated collection [illegible] character studies prepared for the Fourth Internatio[illegible] Congress of Neurology To provide in a single vo[illegible] succinct accounts of 133 of the masters of neurology, written by their admirers and in some instances th[illegible] pupils is an achievement of note

It is salutary to be reminded of the prodigious output [illegible] work of Ramon y Cajal of J E. Purkinje (who had to wa[illegible]

years (for his long wanted microscope), and of the versatile Heinrich Obersteiner We read of the stoicism of the youthful Nicholas Achucarro, a victim of Hodgkin's disease, and of Alfons Maria Jakob, a tremendous worker, who suffered for his last 7 years from osteomyelitis and died at the age of 47, and of
teste rseverance of August Forel, who, when most men
sion have surrendered to fate, learned after a stroke to
adrer ft handed, and continued at work for another 19 years
The } Bonin portrays well the polite and genial Rudolph
taneou on Kölliker, who retired from his chair at Würzburg
occurrec) of 85 after publishing twenty papers in his last
continu office Tribute is paid, too, to the memory of
when th alter Campbell, who, fired by the encouragement
with adi gton, did his important pioneer work on
were fo opography in the lonely laboratory of Rainhill
irra
pro cess has come to neurologists for different reasons
in ot and others lived in the heroic age of neurology,
due io made full use of the unparalleled facilities of the
rière at a time when the paralysed were in need of
classification The important contribution of George
Huntington was made in general practice The
Th of Alois Alzheimer, who died at the age of 51, lay in
the pt that he combined the clinical and pathological
fluid h to brain disease Dr A T Rasmussen describes
The efatigable Franz Nissl as "a gnome of a man," a
facilit nd a practical joker, and the portrait of the versatile
comp eir Mitchell, influenced throughout life by Claude
d and also by his vivid memories of the battle of
burg, is ably drawn by Dr Haymaker

Th sidering that these biographies conform to a single
Dr rn, they are remarkably good emphasis has
afte y been laid throughout on an accurate study of
(pri man's character rather than on the bald facts of
urriculum vita Some of the essays are too short
io full justice to their subjects, but the editor, by
ing into the text a running history of neurology,
th done what he set out to do in a most engrossing

causes

choses passionelles

increa JOREL, Médecin Chef des Hôpitaux Psychiatriques
test ons Expansion Scientifique Française 1952 Pp 472
after 2000

in so ppreciate this book fully one needs to be well
cont inted with classical French psychiatry, and with
trop al French literature Dr Borel draws his quota-
stres from La Bruyère or Molière almost as often as
Lasègue, Magnan, or Esquirol The writers,
ver, to whom he turns oftenest are Ribot and
Mlérambault—Ribot who published his *Essai sur*
pap *passions* in 1906, and Clérambault, the brilliant and
of ac clinician who saw in the mechanism of passion
incre creative force giving rise to diverse psychoses,
iltr *ures passionels* He writes in clear and sometimes
latedr nt language of the physical and psychological
prov teristics of passion and of its pathological forms,
brou he discerns in hypochondria and in mystical
chlo as well as in jealousy, revenge, and erotomania
the inical analyses are careful studies of morbid feeling,
ey owe nothing to psycho analysis, as he points out,
a have more in common with Balzac than with
gache Even those who dissent strongly from his
thod and views will enjoy his lucid exposition and
ively critique

Chemical Physiology of Contraction in Body and Heart Muscle

A SZENT GYÖRGYI, PH D, Institute for Muscle Research, Marine Biological Laboratory, Woods Hole, Mass New York Academic Press 1953 Pp 135 $4 80

THIS book is divided into sections (1) introductory
es on the histology and physiology of muscle, (2) the
d lecular mechanism of motion in voluntary muscle,
a study of heart muscle, and (4) some general views about the factors essential to muscle activity Dr Szent-Györgyi, whose outstanding record in biochemical discovery and thought is well known in this country, here stat [illegible] d amplifies many of the almost revolutionar [illegible] on muscular contraction which caused so much discussion when he put them forward in his earlie book, *The Chemistry of Muscular Contraction*

This new book, he says, "is not offered as a comprehensi and objective review, it is the presentation of a problem as he sees it after fourteen years' experiments with muscl He has "endeavoured to talk in a language understandab to the average biologist, stressing outlines more than detai and hoping to be excused by those who prefer a more technic treatment" In these aims he is entirely successful, for he ha written a stimulating and controversial little book easi to be understood by anyone even slightly acquainted wi muscle physiology and biochemistry His rather quai English is here a great advantage, for he eschews pompo and complicated sentences and produces an effect of clarit and charm

The reader will find here the experimental evidence f the conception of actomyosin (the contractile prote element) made up of actin and myosin, of the "mero myosins" of which the latter is composed, and of the part perhaps played by adenosine triphosphate (A.T.P in the contraction process Here is a fascinating stor about the recent work of his school on heart muscle, and exciting hypotheses about the way in which the nervo impulse may act For all who value inspired speculati and who wish to keep abreast of present-day develop ments in muscle biochemistry, physiology, and patholog this book is indispensable

Thinking

An Introduction to its Experimental Psychology GEORG HUMPHREY, professor of psychology in the Universit of Oxford London Methuen 1951 Pp 331 21s

Professor Humphrey, who in 1933 provided us with a thoughtful book on learning, has now written a learne book on thinking This scholarly work covers a wide an fundamental field of psychology, in which it is easy t miss the wood for the trees but Professor Humphrey mastery grasp keeps the material in such proportio that the reader has the main problem always before hi The first chapter deals with association, and argues th the conditioned reflex theory is the modern form of th classical theory of association, against which muc subsequent experimental work was "an unsuccessfu revolt" This is illustrated by the monumental studie of the Würzburg school, to which the next three chapte are devoted The *Gestalt* theory, and the connectio between thought and motor reaction, are next examined A particularly valuable chapter is devoted to languag and thought, a fuller treatment of aphasia would ha have been welcome, but throughout the book the autho has deliberately abstained from examining patholog thinking, except incidentally and briefly The reade concerned with anomalies such as schizophrenic thinki will therefore find no direct reference to them, but a ri supply of theoretical and experimental data many of which throw light on his problems

---

Carbohydrate Metabolism (2nd ed Chicago Universit Press London Cambridge University Press 1952 Pp 336 64s)—This revised and slightly enlarged edition of the well known work by Dr Samuel Soskin and Dr Rachmi Levine will be as well received as its predecessor The authors describe it as a correlative text which brin together biochemical, physiological, and medical knowledg of carbohydrate metabolism in a unique way The claim is substantiated, yet the work remains personal in its presenta tion, stressing, as it does, the authors' particular viewpoints Thus great prominence is given to the rôle of the liver in the control of the blood sugar Besides containing a additional 230 selected references, this edition includes ne material on the interconvertibility of foodstuffs, isotop studies, and hormones—in particular, insulin and the adren steroids As in the first edition there is a good critic account of the significance of *respiratory* quotients, dextrose nitrogen ratios and an excellent review of th mechanisms concerned in ketosis The possible rôle pancreatic hyperglycæmic factor in the apparent action of insulin on liver glycogen has been disregarded, and th discussion of insulin resistance in infections omits any to the adrenal cortex These, however, are small criticisms of a work which will be widely used and appreciated.

THE LANCET

LONDON SATURDAY OCT 10 1953

Our Natural Element

Last year over 4000 people in Greater London lost eir lives in a major disaster This was the fog which escended on the capital on Dec 5 and did not lift ntil Dec 9 No other recorded fog has achieved any ing like this death rate the "smog" in the Meuse alley in 1930 was responsible for only 64 deaths and at in Donora Pennsylvania in 1948, for 20 The creased mortality from the London fog was spread ver the two succeeding weeks and was particularly gh among those aged 45 and over though young ildren too were seriously affected The National moke Abatement Society are as anxious as the rest us that such disasters should not recur, and they pened their twentieth annual conference held at lasgow, from Sept 30 to Oct 2 by discussing how prevent them.

We manufacture our own fogs—wrapping our cities n John Evelyn's classic phrase) in a 'hellish and small cloud of seacoale', but the weather has to ollaborate Under ordinary conditions as Mr A arker D.Sc explained the upper air is cooler than e air near the earth's surface and as the warm air ses there is a constant circulation which produces a reeze or wind Occasionally however the tempera ure at ground level falls below that of the layers ove, which means that no air rises, there is no wind nd if the air is humid fine drops of moisture condense the lower stagnant levels causing a mist or fog In nsely populous and industrial areas sulphur dioxide s and other products of fuel combustion which are rmally dispersed and diluted by the wind collect the stagnant layers in increasing concentration and ve the fog that objectionable flavour and irritating ality so characteristic of the 'London particular

December last year opened with frost and local fogs, llowed by milder weather on Dec 3; then on Dec 4 large anticyclone reached us and stayed until Dec. 8 using frost and fog Milder weather did not reach ndon till Dec 9 The depth of the fog was variable ing 600 ft above sea level at Ranmore Common rrey though Hayes Common Kent which has an titude of only 250 ft., was almost clear for the whole riod; while at Blackheath at an altitude of only 100 ft. e tops of the buses were above the fog for part of the me There was hardly any wind and maximum mperatures ranged from 32° to 43°F The concentra ns of smoke and sulphur dioxide in the air of the ames Valley between Westminster and Beckton from o 2–4, were about the same as the averages for cember 1951 (when there was no intense fog) that is say about 23–71 mg of smoke per 100 c m and 10–21 ts of sulphur dioxide per 100 million parts by volume om Dec 5–8 however the comparable figures for oke were 103–375 *mg and for sulphur dioxide* 47–107 rts—about five times as much as usual In fact There no measurements for carbon monoxide over the riod but wherever there was dense and slow moving affic it probably became high anyhow at the level of r exhausts.

ere were fogs in other parts of the country—notably Glasgow *Leeds, and Salford, but none of them* attained the level of air pollution of the London fog, or lasted so long

Dr J A Scott, medical officer of health for the County of London recalled the results of a study *made earlier this year by Dr* W P D Logan,[1] which showed that in the two weeks following the fog deaths from bronchitis were 10 times as many, from influenza 7 times from pneumonia times from pulmonary tuberculosis 4½ times from other respiratory infections nearly 6 times as many as the average for the three weeks preceding the fog Other patients dying earlier than they would otherwise have done had disorders of the heart and circulation or cancer of the lung and an undue number of infants died from gastroenteritis presumably secondary to a respiratory infection Recent research has shown he said that sulphur dioxide and trioxide in concentrations in the air which are ordinarily non toxic, can when they are carried to the lungs in an aerosol, become exceedingly toxic and kill an animal in 4 seconds This information reached him from Dr Mary Amdur, who, with Philip Drinker and Mr W W Melville reports in our present issue some other effects of inhalation of sulphur dioxide by man While inhaling this gas all their subjects breathed more rapidly and less deeply and their pulse rates rose and one of them was so seriously inconvenienced that the experiment had to be stopped This study also shows that people who work constantly in atmospheres containing appreciable amounts of sulphur dioxide become tolerant of it but this immunity may be achieved *at the cost of a chronic inflammation of the upper* passages and we have no idea what its long effects may be

The risks to which fogs expose us all can be avoided in only one way—by producing less smoke Various measures directed to this end are now coming into action and the society have had a considerable share in promoting them "smokeless zones," for instance were the inspiration of Mr Charles Gandy, a former chairman Dr T Morrison Clayton medical officer of health for Coventry told the conference that at least fifteen local authorities have already obtained the necessary powers in private Acts to establish their own smokeless zones and others have the matter under consideration. The common council of the City of London have recently announced their intention of seeking statutory powers to establish a smokeless zone within the City[2] They intend to prohibit the installation of furnaces in buildings unless these are as far as possible capable of being operated continuously without emitting smoke But any impressive reduction of pollution Dr Clayton pointed out must depend on the extension of smoke*less zones to large areas which must be enlarged still* further over a period of years Manchester has made a beginning by proposing to extend its original smokeless zone to twice its present size and Coventry intends to do more than double its zone which was first established in March 1951 But many authorities *specially those not faced with excessive local smoke* problems are taking no action regardless of the fact that smoke knows no boundaries and that in these days of dispersal of industry factories may hatch out at any moment in their midst

---

[1] *Lancet* 1953 i 336

[2] *Times* Sept. 23

In any case industry is not the only, or even the worst, culprit The domestic hearth, renowned though it may be for nourishing all the solid virtues, is itself no mean consumer of solid fuel one may almost say there is no domestic fire without smoke Indeed family hearths contribute some 900,000 tons—about half the —of our annual smoke output Those who think mokeless zones as applying mainly to industry ccept the awkward truth that if we are to abolish ous fogs, domestic fires must also be taken into This clearly places a duty on the house but it is hard for him to discover exactly at duty is Speakers at the conference offered suggestions first that he should burn only keless fuel, and secondly that he should fit his with modern improved grates which burn fuel completely than the older types In addition urged to use gas or electricity instead of coal whenever the weather permits But at once he nters difficulties The new grates are relatively esive—to buy, or to fit, or both—and so are gas ectric fires True, smokeless fuel can be burnt in in old-fashioned grate without adding appreci- to atmospheric pollution, but then the supply mokeless fuel is not adequate to supply every ehold, and moreover it is somewhat more costly y raw coal

is is surely a very silly dilemma We are in the t of fish whose stream is poisoned by the effluent actory our native element is being made noxious ; and already some of us have lost our lives we indeed fish, stringent regulations would at ome into force to prevent the nuisance It is an reflection that air pollution (with which past vers made several tinkering attempts to deal) probably grown steadily heavier through the uries, so that in this respect we have sunk, ration by generation, into slum conditions Our cities would have shocked our forebears as much heir drains shock us

t is surely time to help the National Smoke Abatement Society to clean the place up According to nmander C BUIST, Mr J O COOKE, Mr ERIC J VID, and Mr H H PROSSER, in their joint paper he availability and distribution of smokeless fuel, should concentrate first on the areas of heaviest ution—Greater London, the Black Country, south cashire, the West Riding, the Clyde, the Tyne, the Tees To eliminate domestic smoke in these , they say, something less than an additional 10 ion tons of solid smokeless fuels would be neces y, and it would be within the competence of the okeless fuel industries to produce that, say, on a n years' plan With support from the Government d local authorities, however, it would be possible to hieve this target in only four years, and to increase the tonnage to 15 million by 1962 Secondly, designs of appliances suitable for burning solid smokeless fuel should be available at reasonable prices and the makers of such appliances and distributors of smokeless fuel should provide an efficient service to advise the householder on the correct installation and maintenance of his appliance, and the kind of smokeless fuel to use in it

Householders have taken kindly to many of the new t f stoves and grates suitable for burning l some 2½ million of them were bought in 1952, so the task of persuading everybody to m them is probably not as serious as some ima Local authorities, it was also suggested, might compensation (as Salford has undertaken to do, to £2 per house) towards the cost of providing modern equipment in houses included in a smok zone, they can see, moreover, that efficient gr are provided in their own new estates Prof. F TYLECOTE, in his presidential address, urged on l authorities their duty of propaganda—by institut more regional committees, forming women's as tions, enlarging smokeless zones and creating ones, forming more "stokers' schools," arran exhibitions, meetings, and broadcasts, and urging th fellow authorities to join in smoke abatement schem Sir JOHN CHARLES, who delivered the fourth Des Vœ memorial lecture at the conference, emphasised great need for research He spoke of Profe DRINKER's plan to reproduce smog in a dis railway tunnel, and to examine its effects on volunteers The deliberations of the committee w has just been appointed, under the chairmanship Sir HUGH BEAVER, to examine the nature, causes, effects of air pollution and to consider prevent measures, may strengthen public opinion, and so the Ministry of Health's medical inquiry, but t wholesome dread most Londoners have of a recurr of last year's episode may well be our most powe friend One way of hastening useful action woul for more of us to join the National Smoke Abatem Society

Doctors and Inquests

WHEN his patient dies in circumstances which for an inquest, what action should the doctor ta His duty is none too clearly defined In tryin meet two interests—that of the registrar of and deaths on the one hand, and of the coron the other—he may satisfy neither

The doctor who has attended a patient in hi illness is obliged by statute to issue a medical ce ficate of cause of death "to the best of his knowle and belief," and to deliver it forthwith to the reg of births and deaths The phrasing of section 2 of the Births and Deaths Registration Act, 1 which has now been re-enacted in a consolida Act, is mandatory and explicit "that practitio shall sign a certificate" Again, under section of the Births and Deaths Registration Act, 19 "Every certificate of cause of death required to signed by that section [i e, section 20 (2) of earlier Act] shall be delivered forthwith by registered medical practitioner by whom the ce ficate is signed to the registrar " It is provided this subsection of the 1926 Act that, if an inq is going to be held, the notice to informant, wh the doctor is also required to complete, need no delivered to the registrar, but as the subs does not mention the certificate of cause of de the certificate presumably must still be deliv This is a change from the terms of the 1874 (section 20 [3]) which declared "Where an inq is held a medical certificate of the cause of d need not be given to the registrar, but the certifi of the finding of the jury furnished by the cor shall be sufficient" (At that time there was no n to informant) There seems little doubt, there at the Registrar General is entitled to the view[1] at "as the law now stands, the duty placed upon egistered medical practitioner [i e, to issue a medical rtificate of cause of death] appears to be unquali d, and unaffected by the fact that he or some other rson has reported the cause to the coroner or that inquest may take place"

Though certain persons have a statutory duty to form the coroner of a death the doctor is not one of ese—unless the patient was certified as insane The roner's claim on the doctor derives from common w, by which "it is the duty of every person who is out the deceased [which includes the doctor] to ve immediate notice to the coroner or to his officer to the appropriate officer of police," who then mmunicates with the coroner[2] This obligation wever, lacks legal force since there seem to be no ans open to the coroner to compel obedience has powers to deal with those who obstruct him the exercise of his duty but this duty, and its incident powers, cannot very well arise until he has en informed of the death The situation has been ther complicated by the growth of a practice which, ough without the sanction of law, has evident vantages many doctors when they cannot certify t the death was due to natural causes forthwith orm the coroner and withhold the medical certi ate of cause of death Obviously it is desirable that, en death is due to any unnatural cause this fact ould be brought to the notice of the authorities at earliest moment and it is clearly better to proceed this way—illegal though it seems to be—rather n permit the relatives to experience the frustration d delay inevitable when the information reaches the oner by the proper but devious route In cases ere death has been caused by a criminal act, cedural delay, even of only a few hours, can add preciably to the task of the police Delay must o be avoided where the circumstances call for a st-mortem examination refrigerating plant for the rage of bodies is scarce and without it post- rtem changes may develop which impede discovery the cause of death

n the existing circumstances it seems that the tor's proper course is to inform the coroner of any th which he cannot certify as due to natural causes, l also to issue a medical certificate of cause of th initialling statement 'A' to show that the oner has been informed. When the doctor does not w the cause the space reserved for this should marked 'not known' or 'uncertain' But the sent situation is unsatisfactory Whenever a tor is uncertain of the cause of death he should specifically responsible for reporting the death to coroner after which any further action so far the doctor is concerned should rest with the oner The coroner should be empowered to enforce nediate notification of circumstances which may essitate the holding of an inquest Furthermore e the coroner has been informed of a death, the tor should no longer be expected to issue a medical ificate of cause of death unless so directed by coroner

---

Annotations

CONDITIONED AND AUTONOMOUS NEOPLASMS

WHEN a chemical carcinogen is applied to the skin the resulting tumour has the character of an autonomous neoplasm in other words it arises and persists after application of the chemical has been discontinued. Two phases of genesis have been recognised: a phase of initiation in which a small proportion of the epidermal cells are permanently altered to latent tumour cells and a phase of development or promotion, during [illegible] the latent tumour cells multiply and induce vi [illegible] finally malignant tumours The phase of ini [illegible] requires a specific carcinogenic substance the ph [illegible] development can be brought about by the action eith [illegible] of a specific carcinogen or of a non specific irritant su [illegible] as croton oil This explains the long latent period betwe [illegible] the application of a carcinogen and the appearance of a tumour It also implies that the primary change takes place in the epidermal cell itself and not in the adjacent or underlying tissues though not everyone agrees on this During the development of carcinogen induced tumours there is a sequence of step like changes from normal epithelium to the subthreshold neoplastic state thence to papilloma, and from papilloma to carcinoma This has been called by Foulds[1] "progression" w [illegible] signifies not merely augmentation of size or of proper [illegible] already present but the development of new and ir [illegible] sible properties along the path of sequence of the ste [illegible] changes Progression may halt spontaneously for a [illegible] time at any point and it does not necessarily reac [illegible] end point within the life time of the host.

In certain circumstances tumours can be ind [illegible] which owe their origin to alterations in the host or the organ in which the tumour arises Furth [illegible] summarised much of the work in this field Admin [illegible] tion of goitrogens interferes with the thyroid pitu [illegible] hormonal relationship and results in the thyroid tum [illegible] by the following mechanism Thiouracil does not in [illegible] the thyroid cells, but it blocks their ability to synth [illegible] thyroid hormone (T.H.) thereby stimulating the pitui [illegible] to discharge an increased quantity of thyroid-stimula [illegible] hormone (T.S.H.) This causes tremendous hyperpl [illegible] and adenomatosis of the thyroid gland These adeno [illegible] can be grafted into animals whose thyroid glands [illegible] blocked with thiouracil but not into normal anima [illegible] The grafts, though dependent on the T.S.H. liberated [illegible] the thiouracil often metastasise to the lungs. Simil [illegible] mechanisms underlie the induction of tumours by inter ference with the gonadal pituitary relationship Wh [illegible] ovaries are grafted into the spleen of spayed animals, th [illegible] follicular hormones are transported to the liver by the portal vein and are there destroyed with a resulti [illegible] increase in secretion of gonadotropic hormones by t [illegible] pituitary This induces granulosa-cell tumours [illegible] luteomas in the heterotropic ovary Many of t [illegible] tumours still depend for continued growth on the pres [illegible] of excess of gonadotropic hormones but others bec [illegible] autonomous within the lifetime of the host

Furth also draws attention to the fundamental part played by hormones in tumorigenesis By analogy with the idea of the dual mechanism of initiation and promotion of tumours it might be supposed that these hormones act as promoting agents By this interpretation however there must also be an initiating agent in the many types of cancer induced by hormonal changes. With mammary cancer in mice such an agent can certainly be found in the Bittner milk factor; but there is no evidence clinical or experimental, for a similar initiating agent in the case of the gonadal thyroid, or pituitary tumours described It would thus seem that the malignant change in these cases takes place through disturbance of the physiological

2 Furth, J *Cancer Res* 1953 13 477

mechanisms by which the hormones produce their effects within the cell, but unfortunately practically nothing is known of the nature of these normal processes

Such observations as these have led to the concept of dependent or conditioned neoplasms, dependency being a phase in the progression to autonomous malignancy ins and his colleagues[3] have used this as the tical basis for advocating orchidectomy or treat with stilbœstrol for retarding prostatic cancer, and enalectomy (with suitable cortisone maintenance) for mary cancer In some cases the primary tumour regressed while the metastases have progressed, er cases both primary and metastases have ed These observations indicate that control of hormonal environment can prevent progression of pendent tumours to ever-increasing autonomy—perhaps a more rational means of saving life than either the urgical removal of established tumours or even the (still distant) prevention of tumours Once more the clinician is being helped by researches which might at one time have seemed academic and unrelated to the problems of one patient

FOOD IN BED

AMONG the useful activities of King Edward's Hospital Fund for London is the promotion of better hospital ring At an exhibition on Sept 30, at the Fund's ool of Hospital Catering (established at St Pancras ital, London, two years ago), visitors had the oppor of seeing hospital meals which had been cooked e students, *under the direction of the chef instructor,* of admiring the care with which they were served idea that food must *look* attractive is fast gaining und in this country, and the idea that it should also delicious must surely follow It was the confident of the chef of this school that his students' dishes ly looked good but had the right taste

the instructional kitchen every student has her own and tools, and four double gas cookers occupy the lle of the room Upstairs are common-rooms, a ure-room and a study, the students live out in gings arranged for them by the Fund Courses are nned for various groups—catering officers and those ut to become catering officers, head chefs and superndents, and cooks and assistant cooks The school o provides refresher courses for all grades of catering ff, arranges catering courses for hospital administrative d nursing staff, and provides a centre for lectures, monstrations, discussions, and conferences relating to aspects of hospital catering

Linked with the school is the Fund's catering advisory vice, which serves hospitals in all the four Metro litan regions, sending to them on request a catering viser, an equipment specialist, specialists in buying d costing, a designer draughtsman, and an adviser on chen management All these had taken their part in exhibition Plans by the designer draughtsmen ed kitchens of many hospitals as the Fund's team found them, and the same kitchens redesigned A model of one of these kitchens made it easy to see ow the movement of a few pieces of equipment or machinery, a partition, a new route for trolleys, and similar simple alterations had reduced pandemonium to order and lightened the load on feet and tempers A display of materials used in the structure and equipping of kitchens—modern types of flooring new types of laminated plastic trays, aluminium alloys for pans, lift cords, bowls, hand tools, and many other things—showed how rapidly design is advancing in this field All these things were explained to visitors by able and friendly members of the staff

Dr Charles Hill, parliamentary secretary to the Ministry of Food, whose short address, tossed together th [illegible] hand, agreeably served, and sauced with a dash of tart humour, would have done credit to any reminded members of hospital management comm (who seemed to be there in force) that they must think the lunch they were given daily in the board was the same as the one being served in the wards, urged them to send their cooks and caterers to school to learn from the instructors and from each o The school is a venture, he said, which deserves all *good will and publicity anyone can give it,* and warmly endorse that view

SUBDURAL EFFUSION WITH MENINGITIS

EFFUSION of fluid into the subdural space is *a recognised complication of bacterial meningitis* young children, and Ingraham and his associates[1] lately described 50 such cases In their series adopted the following indications for diagnostic subd "taps"

> "(1) Failure of the temperature curve to show a progr decline, particularly after 72 hours of adequate treat (2) positive C S F culture after 48 hours of adequate treatm (3) convulsions during the convalescent period, (4) convulsions at any time, (5) vomiting during the conval period, (6) gross neurological abnormality (7) the *impression that the course was unsatisfactory*"

When fluid was found, subdural taps were repeated for 7 to 10 days, no more than 20 ml of fluid removed at any one session Removal of the relieved undesirable symptoms "almost immediate *but despite this relief surgical exploration*, with the of removing encapsulating membrane, proved nec in no fewer than 42 of the 50 patients, and membrane was found

Analysis showed that in patients over the age years effusions were hardly ever found, but in the year of life 60% of all patients with influenzal, me coccal, or pneumococcal meningitis developed sig subdural effusions Ingraham and his colleagues that permanent neurological damage may result these effusions, and they therefore advocate (a) *nostic tap for any of the indications in their comp* sive list of signs, (*b*) repeated daily drainage of fluid, and (*c*) planned craniotomy, with wide ex the subdural membrane

This is a vigorous programme, and there is not enough evidence to justify its general applicatio Ingraham's 50 patients, 13 were treated before sub effusion was systematically sought in all patients, only 1 of these 13 children survived with intact men Of the 37 cases diagnosed during the systematic 22 have so far been followed for a year or more, and 16 of these 22 are rated as normal Ingraham com the results in the two groups and concludes that difference in results points to the value of his meth treatment There are grave objections to compar this kind Moreover, if untreated subdural ef commonly gave rise to cerebral damage, one expect poor results in centres where subdural rarely practised Yet there are many series on in which lasting cure of purulent meningitis has achieved in over 95% of cases, without common re to subdural taps It seems that if effusions occur these cases, then they regressed spontaneously ham's figures show that in more than two third patients whose effusions were tapped an encaps membrane developed later, and it seems possible the taps themselves provoked this undesirable react the meninges

There is no doubt that subdural effusions do purulent meningitis, nor that some effusions neurosurgical intervention Ingraham's routine ical aid in the treatment of at least 60% of small lren with *purulent meningitis There is no place for* tyro between the dura and the cortex a highly ed neurosurgical team will be needed to apply this nique But first a number of questions should be stigated Does the incidence of effusion vary with antibiotics employed with the route by which they given and with the dosage? Do all unaspirated ions persist as encapsulated foreign bodies com sing and damaging the brain beneath or do many ions regress leaving behind them merely some sions as harmless ichnolites? Only careful follow up ies can answer these questions The follow up must neasured in years or decades rather than months, mental defect is notoriously elusive in early child l, while epilepsy commonly matures silently between primary insult and the onset of seizures. [3]

he long-continued study of series of cured cases is a len that cannot reasonably be laid on the shoulders he overworked pædiatricians of this country and ies by a sequence of registrars or assistants are ilable Perhaps the responsibility may be brought to with the new Clinical Research Board

RESETTLEMENT OF DISABLED PERSONS

ARLIER this year the three Ministers chiefly concerned up a Committee of Inquiry on the Rehabilitation ning and Resettlement of the Disabled [4] in this itry and *its findings will be awaited with interest.* nwhile we cannot help thinking that the Ministry of our and National Service is presenting some of the s in less than due proportion Its *Gazette* [5] in speaking ie work of industrial rehabilitation units, has remarked , ' the modest experiment which started at Egham December 1943 can be said to have marked the nning of the discovery and use in this country of a set of sociological techniques More recently P H St John Wilson under-secretary in charge of k with disabled persons, is reported to have told the rnational Congress of the World Confederation for sical Therapy [6] that Britain s system of industrial abilitation and resettlement of the disabled is in ance of any nation s in the world—a statement which vely does justice to the pioneer work on resettlement e in Denmark and certain other countries years re there was any official machinery of the sort in tain, or to the current work of the Danish Invalidity rt which *particularly in the case of young disabled* ple [7] has much to teach our Ministry Mr Wilson etted that very few people realise that in this field ndeavour we are right out in front. This lack of reness of our achievements, he went on extends ortunately to doctors almost as much as to any section he lay community If the medical profession could only one per cent. of their attention to this sphere st of our resettlement problems would be solved.

: if Mr Wilson cares to read the history of work on resettlement of the disabled in this country he will l *that the medical profession was working on resettle*-it before his Ministry began to think about it. It the report of the British Medical Association Com tee on fractures [8] that stimulated the modern interest the subject—an interest which led in time to the ing up of the Interdepartmental committee which in n prepared the way [9] for subsequent administrative ion Nor must it be forgotten that long before the eption of the centre at Egham Mr F A Nicoll was using with conspicuous success at Berry Hill Hall in the *reablement of injured miners, the techniques subsequently* adopted at Egham or that the L.M S centre at Crewe the Seamen s Hospital at Greenwich and a number of other centres up and down the country particularly in the coalfields were doing similar work

Today 78% of all recruits to industrial rehabilitation units come from ' medical sources ' which does not suggest that doctors are unaware of the Ministry s work. *If they appear to be lukewarm in their enthusiasm for* its activities in the resettlement of *the disabled the reason* may sometimes be that they have been discouraged by its failure to give effective help to those patients whom they have referred to it. Of the hundreds of thousands of persons on the official Register of Disabled even allowing for those whose disability scarcely interferes with working capacity there are many who need help which they cannot in fact obtain In a large series of disabled persons studied *by Ferguson and MacPhail* [10] *few had received training in* new work suited to their disability yet of 728 who were out of employment when the study was made over 70% had worked less than half of the time since they registered as disabled persons from one to four years previously and 40% had never worked since registration Those who registered on the advice of doctors fared no better than the others The lack of suitable vocational training geared to a prospect of employment in suitable work at the end of training is particularly serious in the case of disabled young people.

One gap in our care for the disabled has lately been filled by the Ministry's offer to help local authorities to set up and maintain workshops for severely disabled people [11] Subsidies of this kind are already given for workshops for the blind and this provision is now being extended to sighted people who are severely handicapped But there is still a long way to go before the official machinery for the settlement of disabled persons in suitable work is as good *as it ought to be in this country* This is a matter in which there must always be a large medical element and to which medicine has undoubtedly a major contribution to make perhaps the findings of the present committee of inquiry may point the need for fuller recognition of the medical implications of disability and the employment of disabled persons than has some times marked the administrative approach even over a decade of full employment.

MICROANGIOGRAPHY

THE term microarteriography [12] or microangiography [13] refers to the technique of radiographing the contrast filled blood vessels of an organ in such a way that the finer vessels are seen when the radiograph is enlarged Microradiography a somewhat ambiguous term is the technique of producing radiographs that can be enlarged and the information obtainable from microradiographs of biological material has been well reviewed by Engström [14]

The difficulties of producing microangiograms limit *their usefulness to thin organs or sections of organs* and since relatively long X ray exposure times are needed, the method is at present virtually useless in the living subject unless the organ is very small and accessible The technique is useful because it may reveal the vascular anatomy of tissue a little thicker than that which can be conveniently studied by ordinary histological methods The tissue must not on the other hand be too thick for then the wealth of detail may be self-obscuring and it may be impossible to see the trees for the wood Microangiography depends on radio opaque contrast media and X rays, whereas more standard methods depend on coloured injection masses and light. The

injection of any contrast substance into the vascular system during life may fail to show individual vascular channels if, at the moment of observation, the contrast medium is not flowing through them in sufficient concentration, or if with the method of display the definition is inadequate Similarly, injection masses in necropsy material may for various reasons not demonstrate a given vascular channel, even though this is patent

Microangiography may often be a useful ancillary method,[15 16] but equivalent results are usually obtainable by other techniques Should it prove possible in the future to take rapid serial angiograms of organs in life which can then be enlarged, then this technique may sometimes yield information that is otherwise unobtainable

ASSESSING A COUGH SUPRESSANT

The obvious way to test the value of a cough suppressant drug is to give it to patients with coughs and observe the result This is the method that Cass and Frederik[17] have adopted in a trial of the new antitussive agent, dextromethorphan But their study shows that even such a simple experiment must be conducted with extraordinary care Their plan was to have the patients themselves, their nurses, and their own ward doctors record the severity of the cough four times daily, on an arbitrary numerical scale from 0 to 4 During a 45 day period the patients received medication four times daily with various substances, the nature of which was unknown to themselves and to the other observers These substances were dextromethorphan hydrobromide, codeine, and an inert tablet —the last two representing positive and negative controls Three batches of each substance were prepared, and each of these nine batches was identified solely by a code number Every patient received successive 5-day courses of each of the nine batches, the order in which they were given being decided at random and differing for each patient For a study on this plan to be statistically irreproachable, the nine batches should be given in every possible sequence, but this requires the participation of 362,880 patients Cass and Frederik were content to screen 1400 patients, from whom they selected 160 as having a cough of suitable degree and duration For one reason and another in only 65 of these patients were records completed The observations made by the patients and nurses had to be rejected because of gaps This left only the records made by the ward doctors, and even these were not above suspicion One such observer is reprimanded by the authors for cheating—he apparently kept a box score of his observations in an attempt to decode the drugs prematurely—but, once this was dealt with, " no personal feelings were allowed to colour any of the observations " Eventually a series of over 11,000 numbers was obtained, representing the cough severity in 65 patients for four periods a day during 45 days It might seem that the effectiveness of the three substances could then have been compared by adding all the numbers obtained for cough severity for each substance in turn But the statistical analysis showed that such a course would yield a fallacious result, because the differences in cough behaviour between individual patients receiving the same medication were greater than the differences in the same patients receiving different drugs When allowance was made for this variation by an appropriate mathematical manipulation a further difficulty arose One of the three batches of dextromethorphan was found to be apparently less beneficial than the placebo This evidently was the price Cass and Frederik had to pay for reducing the number of patients belo statistical ideal random selection had resulted in particular batch of drug having followed codeine frequently in the sequence of administration than the other two batches But the conclusion finally d from this study cannot be seriously questioned it is dextromethorphan hydrobromide in a dose of 4 mg an effective cough suppressant, with about half effectiveness of 17 mg of codeine Cass and Fred think that 10 mg of the new drug may have same effect as 17 mg of codeine

The pharmacological interest of this work is that d tromethorphan belongs to the new series of morph substances the members of which exert some or a the actions of analgesia, central depression, addic liability, and cough suppression The synthetic anal racemorphan (' Dromoran '), the best known member this group, is related to dextromethorphan chem much as morphine is related to codeine Dextrometh phan has been shown to be devoid of addiction liabili and to cause no central depression[18 19], and this la study confirms that the definite antitussive action o 4 mg dose of the hydrobromide is unaccompanied side effects

THE SHORT BIRTH CERTIFICATE

The fear that short birth certificates would be so only by those whose parents were not married, and would become tantamount to certificates of illegitima has proved to be quite unfounded A subcommi appointed by the Magistrates' Association,[20] to inq into their use, draw attention to the study made by Registrar-General between the end of 1947, when certificates were first issued, and 1951 This showed for local offices, the proportion of short certificates from 40 5% of the total issued in 1948 to 62 5% in 1 At Somerset House the rise was less striking ove same period from 26 2 to 30 4% , but even th sufficient to ensure that the certificates are not l sought by the illegitimate alone From the end of until the end of 1952, about 4 million short certific were issued , and there were only 2 million ill people in England and Wales at the time, not all of had had occasion to get birth certificates Thus evident that legitimately born people had felt no di about taking the shorter form

The subcommittee are still concerned, however, ab the position of foundlings, whose certificates car statement that they were born " on or about " such such a date , and this might reveal them as fo to the informed or the curious Similarly, short cert cates issued to children who have been adopted give the country of birth and not the district, which c betray them as being adopted children The comm is considering ways in which these aberrant type certificate may be brought into line, thus supporting principle of a fair start and no favour

URTHER ADVANCES IN PATHOLOGY *

DOROTHY S RUSSELL
, Oxfd, M.D Lond Sc.D Camb LL.D Glasg F.R C P
CTOR OF THE BERNHARD BARON INSTITUTE OF PATHOLOGY
NDON HOSPITAL PROFESSOR OF PATHOLOGY IN THE
UNIVERSITY OF LONDON

HE hope with which we peer into the future at any
is apt to be tinged with a certain amount of anxiety
both emotions are heightened when evolution is
d At such periods it is useful to examine the main
of evolution and to discuss them as frankly as
ible. By so doing we may in some fashion shape
course and avoid certain pitfalls

o-one is likely to challenge the assumption that
ology will continue to make important advances
he near future in respect of acquired knowledge
n however, less concerned with this aspect of progress
he present moment than with the practical problems
ted by the growth of knowledge, and consequent
ialisation I propose to discuss some of these
blems, and to suggest a few possible ways of mitigating
difficulties that already threaten the organisation
ur various branches of study

HISTORICAL BACKGROUND

he development of pathology up to the present
tury and *its subdivision into different branches, is a*
iliar story and therefore one upon which I do not
pose to dwell at length It will suffice to remind
of a few facts.

orbid anatomy is as old as medicine itself and until
middle of last century was practised by the clinician
was thereby enabled to correlate his observations
the bedside with the naked-eye appearances of dis
ed organs Keen observation backed by intelligence
ded a rich harvest at the hands of such as Richard
ght, Addison and Hodgkin—to mention a few The
jection of morbid anatomy to the subtler processes of
opathology, and the microscopic analysis of changes
with the naked eye led to the establishment of
oratories with all their paraphernalia including the
rarchies *of academic and technical staffs* This
ed the way to the transference of post mortem dis
tions from the hands of the clinician to those of the
hologist Not without local struggles however
ause many clinicians set great store by this first
d experience In the early part of the present
tury the physicians at the London Hospital habitually
formed post mortem examinations and, in that
acity were dubbed visiting pathologists. Their
its lacked punctuality and their dissections were not
ays edifying either to the medical students or to the
hologists who had to report upon the results! My
decessor Prof H M Turnbull insisted upon
ctuality and whether it was due to this ruling
ich I am sure he enforced) or to the meticulous
hnique which he imparted from his previous studies
Dresden or perhaps to an access of wisdom it
hard to say but the attendance of the visiting
thologists ' gradually tailed off After the first
rld war there was only one to my recollection who
t in a regular appearance for this purpose But his
ctuality and standard of performance were both high
was a welcomed ' visitor

At this time it was rather fashionable to write off
topathology as effete The objects of our study
neath the microscope were held to be conglomerations
artefacts moreover the Germans had mapped out everything of importance, and little remained for discovery Never was a judgment more erroneous! At the present time new fields are opening out in histochemistry and cytochemistry and new kinds of microscope reveal structural details that were hitherto unknown Fresh aspects of disease are constantly appearing for various reasons they demand vigilance and adequate investigation.

The rudiments of what we call *clinical pathology* are of equal antiquity if we include the gross examination of various secretions and excretions But clinical pathologists and the laboratories sacred to them are of recent date They often started their existence in a hole and corner fashion within the larger hospitals at the instigation of honorary consultants who realised that such laboratory services could be of value to them Such at any rate was the mode of origin at the London Hospital The amenities provided there have been described by the late Sir Philip Panton, in his *Leaves from a Doctor s Life*[1] as ' a single room together with a staff of one extremely ignorant technician When it is recalled that this was the meagre beginning some fifty years ago the rate of subsequent development has been startling In particular we may note the extraordinary importance of hæmatology which bids fair not only to establish itself as a separate discipline but even to indulge in subdivisions of its own

In *bacteriology* we have witnessed a similar kind of growth and specialisation The late Professor Bulloch who occupied the chair of bacteriology at the London Hospital Medical College from 1919 to 1934 used to give lectures in general pathology As well as being an eminent bacteriologist he was in fact a sound pathologist with a wide knowledge of the various branches as they then existed. In his early days he was a student of neuropathology, and he retained his interest in the silver impregnations for neurofibrils and axis cylinders I possess an elegant preparation of Auerbach s plexus made by him as a by product when he was working on the sterilisation of catgut a few years before his retirement But today the academic bacteriologist may devote himself to the study of viruses, or immunology or to some other aspect of microbiology His terminology is so specialised that it is often difficult for others to take an intelligent interest in his scientific communications His opening gambit is often a complicated table thrown upon the screen with the minimum of preamble, which (to quote the late Prof E H Kettle) provokes an antibody reaction in the unversed beholder! I shall revert to this matter later

Chemical pathology came relatively late upon the scene Founded upon organic chemistry which itself underwent systematic development in the 19th century the subject was still in embryo until after the first world war when colorimetry came into its own and greatly extended the scope of chemical analysis of the body fluids. A number of other refined methods of analysis have recently come into use Chemical pathology is still engaged in the struggles bound up with its expansion, and emancipation from a position subordinate to clinical pathology

THE TENDENCY TO SUBDIVISION

At the present time therefore we are all fully aware of this steady and rapid growth of the various branches of pathology and the tendency of those branches to *subdivide into further subgroups or specialties* We recognise also that this tendency is not peculiar to pathology but is a general feature of medicine and indeed, of other sciences The situation in medicine as a whole has been examined by Sir Russell Brain in his annual oration to the Medical Society of London[2] He traces the ways in which the various clinical specialties have become separated—a process of disintegration and differentiation Side by side with this there are certain points at which reintegration takes place, owing to the necessity for mutual aid in diagnosis and treatment amongst the specialists

* residential address delivered before the Association of Clinical Pathologists on Oct 2

[1] Panton, P N Leaves from a Doctor s Life. London 1951 p 131.

[2] Brain, W R. *Lancet* 1953 i, 959

We have heard much, in recent years, of the necessity for integration and synopsis in relation to medical education But, although we may have subscribed in theory to the proposals made by the learned authors of sundry reports and memoranda, I submit that so far little attempt has been made to put the advice into practice This is explicable because a reasonably integrated presentation of medicine, including of course pathology, is not feasible unless those responsible for the growing points of knowledge—namely, the active researchers—will undertake the responsibility for integration amongst themselves This point needs further elaboration

THE SPECIAL PATHOLOGIST

Since the practice of pathology necessarily goes hand in hand with clinical medicine, it follows that special lines, for example, neuropathology and ophthalmic pathology, have tended to be segregated in hospitals devoted to these specialties In past decades the pathology at such hospitals was often unsatisfactory because the office of pathologist was occupied by the aspirant to a clinical appointment He therefore used the laboratory appointment, which was generally part time, merely as a stepping-stone The main brunt of the laboratory work was borne by a senior technician who often acquired authority to a formidable and unhealthy degree ! This arrangement has properly given place to a system of full-time and permanent special pathologists Their segregation, however, carries with it certain dangers to the interests of pathology as a whole, and this, I think, applies particularly to histopathology In the first place they may fail to appreciate the importance of correlating their observations with the pathology of the body as a whole They sometimes in fact become curiously detached in this respect I once overheard, in a neuropathological laboratory, a somewhat contemptuous reference to the extraneural tissues as "the trunk tissues" Another menace lies in the elaboration of special nomenclatures which tend to alienate their users from pathologists in general Ophthalmology is a conspicuous example of this habit Amongst neuropathologists there is an affection for German terms, or for literal renderings of German expressions, in their special nomenclature This is confusing for others and appears to me absolutely unnecessary There can for example be no excuse for the use of the term *Gitterzell* when the perfectly good equivalent of "foam cell" is ready to hand, or for the description of a loss of neurones from some part of the nervous system as "an outfall" I would plead therefore for the simplification of nomenclature, and the application of terms in general use to special instances whenever possible And this recommendation applies not merely to histopathology, whence my examples are taken, but to all branches of pathology The alternative development will simply lead to a confounding of language—in other words Babel—in which none will understand what the others are saying

Were it possible to wipe the slate and start afresh, there would be a strong argument in favour of the development of such special lines as pædiatrics, neurology, ophthalmology, and so forth in intimate association with institutions concerned with general medicine In modern hospital planning this kind of centralisation is in fact favoured The arrangement would permit of a centralised department of pathology in which special pathol[illegible] could pursue their separate lines to the mu[illegible]ntage of all From personal experience I can testify to the advantage of this, since I practised neuropathology as a special line both general pathological department and, later, independant laboratory segregated in a neuro unit The latter arrangement carries certain undo benefits both to the pathologist and to the clin But on balance, since there must necessarily be a c between these alternatives, I think the greater adv lies in having the neuropathologist (or any other sp pathologist) incorporated as a unit of a larger de ment of pathology, with whose personnel a exchange of views and criticisms is possible It be recalled that this was also the recommendatio the Goodenough Committee in 1944[3]

This recommendation needs further empha account of the growing tendency towards speci tion on the part of hospital clinicians, and the fact these clinicians are turning with increasing eage towards the laboratory for help They recognise that histopathology, far from being effete, has great potentialities in illuminating the obscurer co of clinical study The close coöperation of clinician pathologist has indeed become more than ever tive Unfortunately, however, the routine hos pathologist has neither the time nor, in many resp the necessary background of knowledge to satisf these requirements He may, and often does, de such time as he can spare to research in one p specialty Thus the only satisfactory solution be the employment of as many pathologists as importunity of clinical specialists may demand for solution of their problems But neither space money are available to implement this either n in the immediate future

SCIENTIFIC COMMUNICATIONS

I must turn now to other questions arising directly from research and, in particular, the c munication of the results of research to others. We faced with difficulties arising both from the rapid in the membership of our societies, and from the character of the communications read at meet The Pathological Society of Great Britain and Ire is now so bulky that it is usually necessary to split programme in two concurrent parts, thus divi the bacteriologists from the rest Both are thus dep to the detriment of both But this arrange loudly regretted by so many members of this soc is a kind of segregation that is sometimes activ sought by other groups in pathology Thus a few ago there was a bid to set up a separate section hæmatology in the Royal Society of Medicine. Ma of us felt this to be undesirable since it would weakened the section of pathology Again, wi recent months, an Association of Clinical Biochem has been created While the council of the Associ of Clinical Pathologists has formally welcomed this step, it is ardently hoped that it will in no way im the participation of the biochemists in our more ge meetings

There is of course nothing to prevent any group specialised workers from forming a society for purpose of discussing their own particular problems, much profit may be derived from such discuss But I hold that no specialised society of this kind sh detract from the membership of, and active participat in, more general societies We may indeed visu a possible evolution of our societies whereby those more general character and membership may come exercise their most important function as a medium the interpretation and correlation of the growing po of knowledge I look forward, in short, to a phase velopment in which experts will probably herd together numerous small but highly specialised societies They ll doubtless air their views in terms incomprehensible others But the more clear headed and thoughtful these experts should be able to present the results a general gathering of pathologists, using terms that e majority at least can understand and relating any vances made both to basic principles and to cognate sciplines. In the meantime we may flatter ourselves at the Association of Clinical Pathologists incorpora g as it does all the main branches of pathology that applied to clinical medicine is of the greatest value holding together our various interests and in main ning a nice balance between academic and non demic practice

---

[3] Report of the Interdepartmental Committee on Medical Sc H M Stationery Office 1944, p 141

ROUTINE AND RESEARCH

At this point I should like to say a few words to patho gists of the non academic category Perhaps they metimes feel that they are overburdened with routine rk and that research is outside their orbit There , however *notable exceptions, as we well know* e combination of routine work and research is in elf admirable and all routine workers should command fficient technical and other support if they are inspired carry out original investigations. In many instances s support is wholly inadequate I gather however n the columns of the *Manchester Guardian*,[4] that the nister of Health recognises the prime importance of veloping laboratory facilities in order that this country y not fall behind in the field of investigation We y hope therefore for further expansion when restric ns on capital expenditure are relaxed

It is perhaps insufficiently appreciated that academic thologists, on the other hand are often too over rdened with routine duties to give such attention to *ginal work as is demanded by the universities* But is common knowledge that advancement is only ined by means of substantial publications Hence bloated condition of our journals and the congestion editorial desks. In fact Alan Gregg[5] states: I ow of one department in an American University ere the value of a man was estimated by the number pages he had published divided by the number of ars he had possessed the PH D degree It was a partment of psychology Research is surely a oured conception at the present time, and an umbrella much that is inept On the other hand there exists inspired researcher who would worthily fill a chair t who rejects this proposition from the knowledge t acceptance of professorial status, with its inevitable rden of administrative work would prove crippling his main interests Sacrifice of position and financial ward is the penalty for his decision.

THE WHITE PAPER AND ITS CONSEQUENCES

Such a situation calls for remedy and we may hope m the recent white paper on clinical research[6] that solution is within sight In the first place it recom nds arrangements for decentralisation enabling spitals to promote research with the greatest possible edom and without detailed supervision Secondly rejects the principle that the research worker should paid less than the clinician thus the man who has genuine flair for research could look forward to the spect of a research career without the sacrifices viously entailed

The various branches of pathology must surely be ected by these proposals There are few forms of clinical research that do not involve extensive laboratory investigations and one may perhaps envisage the future director of research as a person who has been so well trained both in the wards and in the laboratories that he can coördinate the researches of juniors who are working in either In the sphere of pathology we probably are all acquainted with the man who has the ability and inclination to do whole time research but has no wish to be segregated in an institute which is entirely detached from hospital work His interests lie in the application of his observations to clinical problems He must therefore attach himself to a hospital to gain the stimulus and the opportunities required But at the present time there is virtually no provision for a worker of this kind. A few research fellowships are available here and there their tenure is usually limited, and the salaries attached of an order that anyhow opposes long tenure It is obviously unreasonable that whole time research should entail celibacy These research fellowships should serve a valuable purpose as a testing period for those who show promise and are gifted with the various attributes that we regard as desirable in a prospective researcher But when the testing time is over and a reassessment shows that the candidate has proved himself a permanent post at advanced remuneration should be his reward. Reverting to the white paper we must like Mr Micawber hope that something will turn up !

Finally I should like to notice the recommendation of the white paper that the central research organisation should be empowered to make when necessary arrangements for work abroad Either individual researchers or units might profit in this way The profit would also extend to the centres visited in the case of those that are geographically isolated or lie in the more backward countries This conception is in close harmony with views expressed this summer at the Cambridge Congress of Commonwealth Universities An increasing degree of free movement of scholars between these constituent universities would confer an inestimable benefit not only upon the scholars themselves but also upon the growth of mutual knowledge good will and understanding In pathology we are aware of many racial and geographical variations in the pattern and kinds of disease *These demand investigation not only for* their own sake and for the sake of those who suffer thereby but also because their study would doubtless lead us to a better understanding of our own diseases

Our outlook and teaching in this country are far too parochial; the enrichment gained by periods of work abroad is, in my view a target that we should set as a desideratum for all Before settling down it would be no bad thing if it were obligatory for every young pathologist to undertake a spell of study and if possible research in some other part of the Commonwealth as part of his training Were this accepted as a general rule the fear of being forgotten, or of slipping off the academic ladder would lose its force And doubtless it is that fear as well as the present absence of any proper financial provision that has inhibited the otherwise bold spirit from embarking on a venture that might prove so profitable to himself and to human society

THE ASSOCIATION OF CLINICAL PATHOLOGISTS

There are doubtless many aspects of my subject that have been left untouched, but I have *said something* of those that appeal to me as most important And I have chosen this occasion for the purpose from my conviction that it lies more within the power and scope of this association than of any other body to maintain the integrity of pathology in the face of growing diversification

The Widdicombe File

III ORGS ?

MY DEAR WHIDDON,

I owe an apology to you and to your house surgeon To him because I rebuked him more sharply than mere ignorance deserved, and my only excuse can be that his youthful appearance—is there still a minimum age for medical registration ?—brought out the old dominie in me To you because in rebuking him I usurped your locum parentis (or locus ?—a nice point of usage) I should have remembered that it is your custom to include good manners and common sense as part of the education of the young surgeon

The young man reflects little credit on his previous teachers I am accustomed to those who use my laboratory as a sort of penny-in the slot crystal ball from which all the answers to their silly questions may be obtained in a twinkling, but on that morning I was out of sorts and jibbed at the specimen of fæces accompanied by the bald query "Orgs ?" Do you blame me if I returned the immediate answer "Present" ? I hoped that by this brutality I might impress on his mind that useful answers are possible only to useful questions—but the blame is not his I have little doubt that bacteriology is the worst taught subject in the curriculum It takes up a good deal of time which the student might spend better in the wards and leaves him with some ill-digested applied botany, a lot of names learned by rote, and the illusion that if he sends any specimen to the laboratory he will receive the correct diagnosis on a plate without further effort If it is taught apart from general pathology —as it usually is—he forgets that bacteria by themselves are no more harmful than puddocks in a pond Because they are "classical" he learns a lot about typhoid and plague bacilli and the pneumococcus as parasitic members of the vegetable kingdom, but about whitlows and inflamed tonsils very little and he seldom knows how to immunise his own child against diphtheria Do you still devote much time to teaching the surgical treatment of aneurysms ? Because bacteriology in the medical school is divorced from medicine and surgery it is only after years in practice (or six months as your H S) that he learns that the findings of the laboratory are no more than physical signs, of the same order of truth as those which he detects with his own eyes and hands Their diagnostic value resides not in any single one of them but in the sum total

* * *

If I were to return to teaching perhaps I could not do much better I am not frightened of the vested interests of those who earn their bread that laborious way or of those who collect the fees from examination candidates The truth is that I hardly know enough bacteriology in its applications to medicine to let me teach it without a good deal of misgiving If I am injecting a mouse with anthrax bacilli and I let the needle slip into my finger I know I have done a foolish thing, but I also know from experience that I am not bound to suffer an infection Do you remember our happy meeting—happy for me at any rate—in Deolali on our way home from SEAC ? We both wished to buy some ornamental trash as evidence that we had in fact seen the glorious East, but the bazaar was out of bounds because there had been two cases of bubonic plague there Now I will bet my boots that that bazaar held all the textbook essentials for a thundering good epidemic—humans and fleas and rats beyond the dreams of a rodent exterminator's avarice—and there were just two men suffering from plague [illegible]hen I used to give my lecture on plague to the [illegible] I used to tell them to read *Martin Arrowsmith*, but I am glad that none of them me the questions I asked myself in that bug-i tent

Contrariwise the other day I saw an outbr infectious disease which should never have happe all—according to the books An entire resp middle class family were prostrated with a sal infection The housewife set a standard of cle which I seldom see in my own home (I trust discretion), they had had no visitors, they eaten elsewhere, their food came from the sam as did their healthy neighbours', and they touched duck eggs or mutilated meat or any suc Students learn about natural and acquired and minimum infective doses I wonder ho teachers add that as far as our knowledge go none of these things explains many of the phenomena associated with infectious disease. I am right in saying that no-one really kno touches off a major epidemic Greenwood, w and thought more about these things than m postulated besides the parasite and its host quid—which is a decent and scholarly way of ignorance

* * *

But these are more than subjects for academ tion Twice in recent weeks I have seen in our own maternity block which underlined ignorance

The first arose from that rarity of these days, puerperal infection with hæmolytic streptococ else was ill, patients or staff, but Matron praiseworthy anxiety lest one of her nurses been the source of infection I had foreboding and no doubt she put down my hesitations I yielded—of course—and we looked at the nose swabs from the twenty-five nurses an who staff the block Eight of them harboured streptococci in their throats, but—and this of hard work for somebody else—none of th the same "type" as that in the original suff fact, we never found whence her infection ca book one of the nurses would have been a who had been on duty in the labour ward w similar infection occurred nine months ago problem had left us with another Here we carrying a potentially dangerous organism in in the presence of patients traditionally s severe infections If we took them off du would have to close, perhaps two If we di should look worse than mugs if a seco occurred The epidemiology of puerperal received the attention of some pretty brains since Semmelweis, but I could not ba to Matron on anything better than an guess of the risks involved In the en carriers stay on duty, chewing penicill kept them out of the labour wards infections were noticed Matron thinks of me

A week or two later another patient ra after delivery, and, as is usual and prope swab from her cervix I found a little pus culture grew *Bacterium coli* and *Streptococcu* staff, unasked and probably unwisely, foun that both of these were sensitive to ch and with this the patient was treated He way, had subsided before my report rea Were these organisms the cause of her fe did they justify the use of a drug which its dangers ? After the event the answer question is clearly 'No", but the first is a difficulty which I meet every day T e normal inhabitants of the bowel but both are capable causing infections elsewhere in the body Neither is normal inhabitant of the vagina, but my faint memories obstetrics suggest that even the best-conducted labour ves some opportunity for the mechanical transfer of ese organisms from the anus Here we found them sociated with pus, and in my simple way I have always sumed that pus is evidence of an inflammatory reaction oes the trauma of childbirth produce such a reaction is the pus evidence of infection albeit a low grade e? At this point I begin to think about angels on a edle's point. We just do not know if the fever was ue to infection with these organisms and I believe the ouse-surgeons erred in assuming that it was In fact gave more weight to our report based on ' scientific " ethods than to the plain fact that by the time he received the patient was very well indeed. I see this impulsive ge to treat first and think afterwards so frequently ace we have had the omnipotent antibiotics that I spect some of our junior colleagues of believing that e only good bacterium is a dead bacterium

* * *

The medical wards plague me with requests for the evalent organism in sputum I wish I knew how is heresy arose. Much of what is labelled sputum ' of course saliva but I will overlook the difficulties hich arise from this Until I am blue in the face I have inted out that the prevalent organism as seen in a ained film of the material is seldom the organism most umerous in my cultures Let me choose the medium d I will give them pneumococci or coliform bacilli or asts for an answer The physician's assumption is, I ppose that the most numerous organism is the one hich is causing the patient's illness and that if he can terminate it with this or that expensive antibiotic the or chap will get better I am not competent to discuss e second part of the argument but my experience has en that the commonest effect of antibacterial treatment one has been to replace one organism with another most as likely to cause disease If I judged by numerical evalence alone I would not give much weight to the bercle bacilli in an open cavity

In appraising the bacteria in sputum we are guided by e analogy of infections elsewhere in the body and by e dogmatic simplicity of the textbook which labels me organisms pathogenic —pneumococci and influ za bacilli—and some saprophytic There are, I lieve very few organisms—tubercle and perhaps thrax bacilli—whose presence in the sputum is evidence r se of disease The great majority—whatever their bels in the book—can enjoy a parasitic life in the human ndpipes if the environment is suitable. In the sense at a staphylococcus causes a boil I rather doubt if y organism causes chronic bronchitis If I am ong I do not know of any evidence derived from rasite or host which will let me put the blame on the ght shoulders. Perhaps they all have a share in the ork We know next to nothing about bacterial symbiosis d I sometimes wonder if the flora of the bronchial tree es not play a part akin to that of the bowel—a part gely beneficial to the owner of the tree Perhaps the ect of a few doses of penicillin on the man with chronic onchitis is rather like that of a few days on yoghourt— stirs up the flora like a gardener with a hoe

* * *

Being a hospital bacteriologist is a very difficult job the golden age of bacteriology—say up to 1906—it s the Pasteurian dogma of specificity which made the lence so exciting and so satisfying Like causes like ere are two patients who suffer from what appears to the same ailment the microbe—an old word not used enough—common to both will be the responsible agent (The biggest blob was beriberi, and the evidence for its infectiousness was better than most people think) Nowadays specific infections seem regrettably, rare We bacteriologists deal mostly with material from bronchitic chests and dirty wounds and—saving your presence—ancient sacculated bladders. Once upon a time we used to spend our days searching for specific organisms—typhoid bacilli or gonococci—to confirm half made diagnoses now we look for an unknown organism which will give a guide to treatment We have all the elegant equipment we can reasonably want We use methods of beautiful refinement and we seldom meet any organisms to which we cannot give a name with a clear conscience Our chief trouble is, I think, that our methods were designed for other ends. Some as I have said, are meant to reveal a specific organism which will confirm a diagnosis —and some work of this kind will always be with us Some—and these are the most refined—were designed to help the epidemiologist. Improvements in culture media let me detect the scanty typhoid bacilli lurking in the carrier's bowel, and for this purpose are better than the older and simpler media When we used to use these I have no doubt that we missed many carriers, but we were no less successful in confirming the diagnosis in an established case of enteric The price which we pay for detecting the single typhoid bacillus is the likelihood of overlooking other organisms of importance which will not grow on these eclectic media This is probably why we were rather slow to spot that certain severe infections of infancy are due to a strain of *Bact coli* indeed I have heard that these first came under suspicion by reason of the smell of the fæces rather than by the orthodox methods of the laboratory (Of course the nose is useful in the laboratory—but don't tell anyone I said so) Epidemiology is an almost unhealthily fascinating subject but its charms have tended to seduce the hospital bacteriologist from his job—which is to assist in the diagnosis and treatment of the sick.

Our other trouble arises from the fallacy that certain organisms are pathogenic and the others are not You can tell the pathogenic ones because there is a list in the textbook, and if I find one in a specimen it must be the cause of the patient's disease. If I cannot find one the disease is due to a virus or is the province of the trick cyclists Of course this is plain biological balderdash but you would be surprised how often I meet it. Pathogenic and saprophytic ' are useful words in writing reports—I use them myself quite frequently—but I really think that they are applicable only to one organism in one site in one patient. I have stroked a lion—with misgivings—and have been bitten by a rabbit.

What we usually lack is evidence of the pathogenicity of any one organism in an individual patient at a given time There are exceptions. The most convincing is the rise in the titre of antibodies in a patient's serum during the course of illness—especially if the same organism can be found somewhere about his person It is an old method which might repay examination if applied to some of the infections which appear to be non-specific.

I am not so far sunk in doubting apathy that I attribute no importance to the meningococcus in the purulent cerebrospinal fluid or the streptococcus in the blood of a patient with the signs of endocarditis I do not really doubt that hæmolytic streptococci cause tonsillitis but I wish I knew if non hæmolytic streptococci do much the same thing I rather think that the botanical origins of our subject and the charms of our technique have led us for too long to look harder at the parasite than at its host—and the second is the way for future advances

Perhaps these will never come Unless we are careful I forsee that we shall be asked to do no more than discover to which antibiotic any infecting organism is sensitive their vulnerability will be more important than their names Indeed today their names are wanted only as a rough guide to treatment Perhaps this is the right way to deal with non-specific infections—it was you who taught me the virtues of Eusol dressings—but it hurts my professional pride I said that bacteriology was difficult I meant useful bacteriology Nothing is easier than to report that a specimen contains these and those organisms and nothing is harder than to persuade myself that I am not drawing a long train of stinking herrings across the paths of truth

* * *

On this poetic note I will end my lamentations and add yet another apology for letting off so much steam (? hot air) and all because I hinted to your house surgeon that he is an ignorant booby He is that and all, and I know that you will exert yourself to correct his failings If you will bring him in to laboratory tea on your next operating day perhaps I may be allowed to help ?

Yours very sincerely,

HARRY HAWKE

Medicine and the Law

Mistakes with Anæsthetics

Two fatal mistakes in the dispensing of anæsthetics were recorded in September

In the first [1] a girl of 19 was undergoing an operation for goitre The surgeon ordered as a local anæsthetic an injection of a solution containing 6 grains of 'Novocain' in 7 ounces of normal saline to which adrenaline was to be added shortly before use As he was dividing the tissues to expose the swelling in the thyroid, a fit developed and the patient collapsed, all attempts to revive her failed The request for the anæsthetic had been communicated to the dispensary by telephone, the dispenser took a bottle of 'Nupercaine', instead of novocain, she explained at the inquest that she had no doubt that nupercaine had been asked for "because we frequently dispense it in saline, whereas novocain is usually dispensed in distilled water" The coroner, remarking that the mistake had been frankly admitted, said he felt that the similarity in the names of the drugs was unfortunate They could easily be confused in an oral message unless enunciation was very clear

'Nupercaine' is a proprietary name for cinchocaine (B P) Formerly 'Nupercaine' was issued as 'Percaine', but this title was changed to avoid confusion with procaine

In the second case [2] a local anæsthetic was being injected into the interspinal ligaments The prescription did not specify the quantities of the adrenaline to be included with the 2% solution of novocain It had apparently been expected that the strength of the solution would be 1 in 50,000 The actual strength was 1 in 1000 A consultant pathologist told the coroner that death was due to heart-failure He had carried out considerable research to ascertain the toxic dose of adrenaline but had no definite results to give It was possible that a nervous patient might secrete adrenaline in excess The practitioner concerned said he had not specified the actual quantity on the prescription, as he thought it was a standard prescription

In both cases a verdict of death by misadventure was recorded Hospital managements will once more be reminded of the constant need of supervision, vigilance, and correct method

Letters to the Editor

CLINICAL PATTERN OF CHRONIC BRONCHITIS

SIR,—The paper by Dr Oswald and others in your issue of Sept 26 interested me greatly I wonder if it would be possible for him, now that he has his team of investigators and questionnaire ready at hand, to carry out the same inquiry in that group of patients which he has discarded as asthmatics Then he could compare these results with his figures for chronic bronchitis. He says—and I can well believe him—that ' some difficulty was experienced in determining the common usage of the term 'chronic bronchitis as opposed to asthma Surely the distinction is not a valid one though admittedly traditional

His paper goes far to confirm me in my view that in fact these two terms designate merely the clinical extremes of a single pathological entity

One visualises the same sort of relation between chronic bronchitis and cat asthma as exists between chronic eczema and, for example acute primula dermatitis Both are allergic reactions and there is an unbroken clinical gradation between the two extremes Secondary infection often complicates and aggravates the more chronic states in each but infection is not the primary cause

The survey brings out many points in which chronic bronchitis resembles the textbook features of asthma

> A relatively high incidence of allergic disorders among the relatives the frequent appearance of respiratory illness in childhood; colds, presumably in most instances vasomotor rhinitis, which " go down to the chest mucoid sputum with prolonged and *distressing morning cough conspicuous* bronchospasm and breathlessness aggravation during winter months and by a number of respiratory irritants and allergens and a high ultimate incidence of emphysema.

The presence of a very strong bee in one's bonnet almost precludes a detached and scientific approach to such a problem at any rate from a statistical angle. Dr Oswald's team would appear to be in an ideal position to tackle it, for he has already selected his asthmatics by exclusion and therefore without any bias in favour of a relation between the two conditions.

Plymouth. W A LISTER

GROUP PRACTICE

SIR,—The two articles by Dr J S Collings (July 4 and Sept 19) present a most interesting and inspiring contribution to present day thought on the development of general practice I should like however to analyse some of Dr Collings's proposals to make some criticisms and to add a few suggestions

As I understand Dr Collings's proposed scheme of basic group practice it is essentially a partnership of up to five men working in common surgery premises for their mutual aid both in consultation with one another and in order that they can help one another during temporary absence on a rota system and that they may be in a position to have more ample and suitable accommodation for their work than is available to one man alone. Also that they may be able economically to employ a sufficiently ample staff of ancillary workers to relieve the more expensively trained doctor of a great deal of his routine work This it is suggested will allow him to use his long training where it is really required

Of course all these are not new proposals What is new is concrete suggestions for putting these proposals into effect and converting vague ideas into a practical working proposition.

Dr Collings also puts forward, as a corner stone of his scheme a proposal for an appointment system of practice I should like to discuss this latter proposal first

Dr Collings suggests a system of appointments of either 15 or 20 minutes If a doctor sees patients at the surgery for a total of 20 hours a week (i e , ten 2 hour sessions, six mornings and four evenings) he will, if all appointments are always filled, deal with 60–80 surgery consultations a week—about 3600 a year For a list of 2500 patients, which is Dr Collings's suggestion, the surgery attendances will be about 1 5 per patient per year This is about half the actual urban figure at the present time Dr Collings suggests that the ratio of "nursing procedures" to doctor's attendances may be as high as 3 to 1, when the scheme is running—by which I presume he implies that on the average a patient will be seen by the doctor on only 1 of his visits in every 4 This would certainly make such an appointment system perfectly practicable, but I find it difficult to accept this ratio One would like to know if Dr Collings is assuming this figure or if he has seen it actually in operation in the urban industrial class practice He appears to visualise a practice in which several nurses are busy throughout the day dealing with "nursing procedures" for patients who were previously seen by the doctor during one of his comparatively brief consulting-hours and who will not need to see him again for several visits

But this is pure phantasy A brief analysis of the last 100 consecutive patients who attended at my surgery shows that I called on my nurse to help me with about 1 in 4, and in not more than 2 cases could she properly have dealt with the patient herself All this does not mean to say that a good nurse in attendance cannot save a vast amount of the doctor's time , but, so far as my own practice is concerned, I cannot see any work for her for long periods of the day apart from the doctor's presence, which is apparently what Dr Collings is suggesting I should like his elucidation on this point

In a description of an appointment system in a mixed general practice which was recently published, 5 minute appointments were attempted and, with some latitude, were found to be workable With ample nursing assistance, I believe 6 minutes per consultation is possible and might be very successful It does, however, rather scale down the type of leisurely, highly efficient practice suggested There are, however, two other difficulties which suggest themselves to me I think a proportion—perhaps a considerable one—of my patients would resent an appointment system Many people do not like telephoning, which in any case is not free like the doctor, and they would certainly not come to the surgery to make an appointment Nearly all "first consultations" would turn up without an appointment and would certainly resent being kept waiting while late arrivals came by appointment and were seen at once The second difficulty is that this system requires attendance at the surgery of a receptionist or appointments clerk for a very large part of each day and I feel that this would be difficult to arrange and very expensive I have come to this conclusion with great regret as I should very much like to see such a system working in my own practice

Apart from the appointment system, Dr Collings's scheme is most attractive and is an extension and elaboration of arrangements which many partnerships have worked out for themselves I feel the greatest stumbling block, as in so many aspects of the health service, is that of finance From my own experience, which covers, on a somewhat smaller scale, much of the proposed layout I am in a position to speak with some confidence on this point I agree with Dr Collings that
each partner should have a separate consulting room
that they can all work at the same time I also agree
h him that a separate small examination room is
uired to each consulting room, and preferably one or
over , 6 ft by 6 ft is large enough for these They
t be sound proof, and for that reason I prefer them
to open direct from each consulting room I also
r rather more waiting room accommodation Apart
these minor points, I am with him
cost of buying, converting, and equipping such a
at least £1700 per doctor It is only because

the older type of dwelling house in our larger t
comparatively inexpensive to buy that the figure
much higher To build new premises is prohib
well as heart breaking One great point in fav
converting the older house is that living accommod
can be provided upstairs, in converted flats, for a
keeper, and for an assistant's or locum's accommod
and this solves many problems without adding mat
to the cost But this cost is nevertheless consid
and I repeat I do not think one can count on less th
average of £1700 per partner—more for small group
a little less for large ones Dr Collings does not
the day-to day cost of running such a surgery

Rates, heat and light, telephone, repairs and ma
insurance, and cleaning may be estimated at abou
year per partner—again a little less for large grou
little more for small ones This is in addition to th
cost of capital finance If all the capital required
borrowed, the annual interest and sinking fund over
may perhaps add up to £130 per year per partner
that the annual cost of running such a central surgery
taken as upwards of £350 for each practitioner using it,
the employment of medical auxiliaries I agree wi
Collings that the optimum number of these is one per
Presumably they will cost about £350 per year each
have now arrived at the figure of upwards of £700
"partnership expenses" for each member of the group
main item under the heading of "partners
expenses" will be the car, which, with depreciation
into account, will probably be at least £450 There
further small personal expenses, and £50 should cover
The total practice expenses are now in the neighbour
£1200 per partner A list of 2500 patients will bri
about £2500 gross, and there will be a little more
wifery and some small private fees My experience
these additions, in urban industrial practice, are sm
dwindling

We find, therefore, that the man wishing to
as his inclination and professional conscience
must spend very nearly half his gross income to
this end , and if, as I agree, 2500 is the maximum
he can properly attend even in the ideal circum
of practice visualised, then his net income can
more than £1300 subject to income tax What
to the mind is, of course, not original the
payment by counting heads is absurd—it simply
premium on the type of practice castigated by
Collings in his original report and places a heavy
the competent and conscientious doctor

At this stage can any useful suggestion be
regarding this ? In my view it can 30% of the
pool is now regarded, for superannuation pur
"expenses of practice" I would suggest that
can be shown, by accountant's figures, to the sati
of an appropriate committee that the propor
expenses in any properly formed and conducted
greater than the general average, on account of
incurred to the substantial gain of their patients
they should receive an additional sum towards
expenses This would, of course, reduce the
capitation fee per head It would tend to sub
efficiency and reduce lists to a reasonable size
realises better than I do that this is a utopian sugg
and I would like to make another, more likely to
substantial measure of support

In my own partnership we have provided for
surgery premises more or less on the lines indicated
Collings For ancillary help we must perforce conte
selves with one part-time trained nurse Other
auxiliaries we must forego, but the central surgery form
seed from which I feel all improvement in general p
grows I do not agree that a group can function at all
premises to practise in It is very likely to do incre
good work if it is once formed and properly housed
necessary capital outlay on housing may suffocate it at
The building societies do not cover quite this need

If a central ad hoc committee were to be set up and
to advance from national funds the capital required

p who could satisfy a committee of the executive council the local medical committee that their proposed scheme urgeries was sound and efficient then I feel such schemes ld be widely put into effect and a great step forward to oving the status of general practice would have been n The central committee might be known as the Practice ommodation and Group Committee It might in many s resemble the present Medical Practices Committee and omposed of general practitioners and lay members who ld have among them a surveyor and a financial expert chairman should I believe be a doctor The advances would control might be loans up to say £2000 per partner a period of 20 years, at the same rate of interest as is paid he compensation money—namely $2^{3}/_{4}\%$ After all the stry have some £30 million of our money still in this fund ne surgery would slowly become the actual property of the p *and a retiring partner could sell his share to a successor* could, in his turn borrow from the fund

e scheme should commend itself to the Ministry since apital cost of providing very suitable surgery accommo n throughout the country would be less than £1 per nt attended and this is perhaps 10% of the cost of th centres which I agree with Dr Collings are quite alistic This cost would be a repayable loan

e annual charge to the partnership including some nursing would be less than 2*s* 6*d* a year in respect of each patient he list and in the experience of those of us who have had good fortune to practise from such a surgery no money ever been better spent

aving once got the surgery the group will at any rate be to use what ancillaries they can afford, and general rovement in practice will come step by step

here is one more point Many of the medical lliaries mentioned by Dr Collings are or should be, ady provided for the patient being paid by other olies of the health service This applies to nurses, th visitors, physiotherapists laboratory technicians

It might be possible to obtain their part time ices at the group premises by proper coöperation in health services where such groups are in full operation.

ne can only reiterate Dr Collings s plea for reorganisa of our work, by ourselves for the mutual benefit urselves and our patients.

oydon Surrey

Reginald N Deane

* Dr Collings s proposals for the financing of group ctices are set out in his third article which we hope ublish shortly—Ed L

LABORATORY DIAGNOSIS OF SMALLPOX

ir,—I feel that your annotation last week on the istry of Health brochure on this subject is a little mis- ing and to some extent dangerous You state e emergence of reliable laboratory tests has reduced erally the period of doubt instead of depending protracted clinical observation in a smallpox hospital an do tests which rapidly and convincingly aid the nosis, often without moving the patient Although his paragraph he refers to the medical adminis- or whoever that may be the word clinician is used equently

t must be recognised that rapidly is a relative n ; a delay of two to three days is frequent, and in a ber of instances laboratory tests may still leave the nosis in doubt A real suspicion of smallpox *must* treated as administrative smallpox and in my ion no specimen should ever be sent to a laboratory out the full knowledge of the local medical officer ealth who is responsible for taking any action he iders necessary Suspected smallpox must be treated mallpox as far as vaccination of close contacts is erned At least one avoidable tragedy occurred he recent outbreak in Yorkshire and Lancashire to waiting for the laboratory report a matter of o days before the vaccination of known close contacts suspected case.

rateful as we are to the virologists for their work his field and the inestimable value of tests properly applied we are already falling into the dangerous practice of dividing cases into suspected ' and confirmed and regarding the laboratory as the only method of confirmation We must avoid in smallpox something similar to the throat swab ' obsession which has occurred in the diagnosis of diphtheria, where the practitioner would ignore even a ' bull neck ' while he waited to obtain a positive swab

POLIOMYELITIS WELSH REGIONAL BOARD AND MINISTRY OF HEALTH

Sir —We have read with some dismay a document just circulated by the Welsh Regional Hospital Board to every consultant asking them to ensure " that the arrangements for the admission and treatment of cases of poliomyelitis in their regions are up to-date and efficient, and reporting a meeting several weeks ago of thirty five physicians otolaryngologists and anæsthetists together with representatives of the Welsh Board of Health the Regional Hospital Board and a number of coöpted members, which recommended that teams should be set up throughout Wales for the treatment of acute poliomyelitis comprising a physician, E N T surgeon anæsthetist neurologist and physiotherapist

Throughout the whole of this lengthy document and its attached memoranda and reports and throughout the whole of its recommendations, there is never one single mention of the orthopædic surgeon, who of course has the responsibility of looking after these patients for the rest of their lives and cannot do it well unless he starts from the beginning

No orthopædic surgeon was invited to attend the conference There was no proposal to include an orthopædic surgeon in any of the teams—only a physiotherapist who bless her heart, would not get far among the otolaryngologists and anæsthetists who are to treat poliomyelitis. No view was sought from any orthopædic surgeon—there was only a report from Dr Ritchie Russell s medical registrar

Orthopædic surgeons who are necessarily tolerant have applauded the recent enthusiasm of some physicians and neurologists in the management of poliomyelitis, especially since the recent epidemic in Denmark which showed so high an incidence of bulbar palsy (though let it be noted, a high incidence also of limb paralysis) even when recent observations and writings have sometimes tended to suggest that only physicians or neurologists are really capable of treating acute poliomyelitis

But when enthusiasm becomes so fanatical that every consultant in one region of the Ministry of Health and *indeed in the whole of one country*—Wales—is advised that no orthopædic surgeon need be consulted on the advisory committee or appointed to any of the special teams and that a physiotherapist will suffice to aid the neurologists, otolaryngologists, and anæsthetists in the treatment of poliomyelitis, it is time to remind ourselves that when this was last done—ten or twenty years ago—we had great disasters and many horrible deformities which could have been prevented but were relieved only after years of surgical treatment

The British Orthopædic Association recognises at once the vital and imperative part that physicians, neurologists and other specialists must play in the treatment of poliomyelitis in its acute stage It knows, too that the life-long treatment of patients with residual paralysis succeeds best when orthopædic management starts early It asks only—and not for reasons of courtesy but only in the interests of good preventive treatment—that consultation and collaboration should begin from the beginning

PAIN IN CHRONIC GASTRIC ULCER

SIR,—I would be glad to clarify some of the points raised by Professor Pickering in his letter of Sept 19

(1) He rightly states that I have postulated physical and chemical factors in inflammatory pain He accepts the chemical but, for two reasons, rejects the physical In my view, these factors, artificially separated for analysis, are in reality inseparable They are interrelated, and react one upon the other Thus, a more efficient and less congested circulation in the painful area involves not only an increase in velocity and volume of flow, and a decrease in pressure, but also a more rapid clearing from the interstitial fluids of the irritating products of inflammation And vice versa, the chemical factors influence the physical—for example, by damaging capillary endothelium

(2) His first reason for rejecting tissue tension as a pain factor is as follows "I should hesitate to base a general principle on one experiment in one subject" But the evidence that tissue tension is a pain factor is based upon a multitude of experiments in a multitude of subjects They include patients with painful inflammatory diseases in whom digital pressure, and dependency and elevation of the part influence the pain, patients who are given injections, by dentists and by medical practitioners, of therapeutic and local anæsthetic agents, and who note an initial pain caused by the prick of the needle, and a second more severe pain which accompanies the injection of the fluid, and which is more marked if the tissue is inflamed, or structurally less distensible They include patients whose pain is relieved by incision of an abscess, or by trephining the nail over a hæmatoma, or the removal of a dental filling over an inflamed pulp The experiments include every systolic throb of every throbbing pain

(3) His second reason for rejecting tissue tension as a pain factor is that the quantity of tissue tension has not been measured But, even in the absence of direct measurements, we can recognise changes For example, that increased function causes increased blood-flow, even though we have no exact measurement of the increase in function, that lightning causes thunder, even though we have no measurement of the electrical discharge Although I know of no technique whereby tissue tension can be directly and exactly measured, it bears a direct relation to the height of the part relative to heart level And this can be measured and expressed in inches as a column of blood This relative height bears a relationship to rate of healing, as well as to pain Alterations in tissue tension are reflected also by the hardening and softening of the parts, and these can be appreciated by the clinical scientist, even in the absence of the instrumental methods of physical science

(4) He doubts whether compression of nerve-fibres is the actual mechanism whereby a pricking or crushing injury causes pain But the mechanism of the initial pain of pricking or crushing, and the doubts about it, are not relevant to the subject under discussion, which is pain due to inflammation

(5) He asks, 'But what events in the stomach and duodenum determine this almost predictable variation in tissue tension ?' I have described these events elsewhere at some length, with diagrams and mathematical proof, but the idea is complex and I fear that I have failed to express it adequately and clearly The 'almost predictable variation in tissue tension,' is brought about (a) by the variations in pressure and flow of blood, which accompany the change from the resting to the active state, and then from the full to the emptying state and (b) by variations in the postural tone or shape of the gastric walls These hæmodynamic and postural changes are themselves brought about by the ingestion of food, its digestion and evacuation But these changes are unequally distributed between the indurated ulcer mass and the more normal gastric wall so that the principle of the Y-tube and other hæmodynamic factors are brought into play, and influence, not only the local circulation of blood, but also the [illegible] and chemical state of the interstitial fluids, [illegible] influence pain

(6) He parts company with me here, because h that the matter is complex, and the evide "nebulous," or as I would put it, incomplete next paragraph he describes the "acid" hypothes shows that the matter is complex, and the ev incomplete If then, a choice is to be made betwe "inflammatory" and "acid" hypotheses, in ea which the matter is complex and the evidence incom I would select the "inflammatory," because the mation is always present in adequate amounts, the acid, and the inflammation has been sho fluctuate directly with the pain periods, wherea acid has been shown not to fluctuate directly the pain periods, although it frequently fluctuates i reverse manner, thus disproving the acid theor Knud Faber[1] and many others have pointed o acidity of the gastric contents becomes higher pain becomes less

Finally, I would like to say that I apprecia data on gastric function collected by Professor Pick and the worth and thoroughness of his ob even though I differ from him in their interp in regard to pain

V J Kin

PERIODIC MEDICAL OVERHAUL

SIR,—The point of view expressed by Sir Ad Abrahams (Sept 26) seems to me to be based incomplete conception of the purpose of period overhauls, and I find his arguments unconvi

He considers, rightly, that the first function o examination is the detection of early diseas surprised that it did not reveal two cases of ver progressive malignant disease and that in a th where it revealed multiple myelomatosis this co be cured There is a stage in every disease befor diagnosis is impossible, and he might as well hav a case of smallpox appearing only a day or two a an examination Likewise, there are still many di that cannot be cured however early they are de But there are many other diseases that are silent i onset yet nevertheless can be diagnosed, and m them will benefit greatly if dealt with at that stage than left until proclaimed by symptoms

Secondly, Sir Adolphe thinks that examinatio form a basis for health education but doubts doctor is the best person to give it In this respe personal individual health education, and who b doctor can give it ?

The purpose of the periodic medical overhaul c considered under these two headings of detection o disease and health education, but I see it from a different angle Many diseases produce few symptoms in their early stages, or the sympto be wrongly attributed by the patient to age, indigestion, overwork, under exercise, or similar One might cite diabetes, hypertension, obesity, tu losis, myxœdema—in fact go through any textbo medicine and see how many descriptions of disease with 'onset insidious" How many patients at early symptoms of malignant disease to piles or or bronchitis, because they are not encouraged to doctor early ? How many women think backa normal or suffer continual fatigue without known because of anæmia from constant menorrhagia ? feet, varicose veins, corns, and a hundred and one defects go untreated because they have been tak granted for so many years A person's real s fitness cannot be assessed accurately by how he he feels

From the point of view of health education, p examinations present a powerful weapon hardly used Preventive medicine must go further than an environment perfect for the average man f

---

[1] Knud Faber K Gastritis and Its Consequences. Oxford

—y widely and what suits one may kill another One y important function of periodic examinations is to the individual to adjust himself to his environment l in a few cases to adjust the environment to the man ain bad habits of living such as over-eating over iking a bad mental approach to trouble domestic ord, wearing unsuitable clothing, lack of hobbies, and ny other matters can undermine health and the lance of a doctor can help to prevent the development lisease attributable to these causes.

t is, of course wrong as Sir Adolphe says to place the phasis on the possibility of disease instead of on lth mindedness but a correctly conducted examina should place the emphasis on health and should do ch to reassure the patient

olgate Surrey ERNEST H CAPEL.

DOSAGE OF ANÆSTHETICS

IR,—In his letter last week (p 733) Dr Galley ears surprised at having achieved anæsthesia for a hysterectomy using only 8 ml of 1 in 1500 solution Nupercaine. He further states I feel quite that few anæsthetists would stake money on achiev analgesia to this height with such small doses given n average patient in the British Isles

would respectfully remind Dr Galley that should he the technique of spinal analgesia described by N C Lake[1] he could obtain anæsthesia for upper ominal surgery with only 9 ml of Light Nupercaine tion for average-sized patients As regards mid al analgesia, 5–7 ml administered by a similar nique, gives anæsthesia up to the umbilicus

inally where spinal anæsthesia is the method of ice, I use and recommend Lake's technique for high mid spinal analgesia whenever possible

ambley Park Middlesex. LOUIS CLEMENT

ROPARÆSTHESIÆ IN THE CARPAL-TUNNEL SYNDROME

R,—Dr Kremer and his colleagues in their admirable le (Sept. 19) have amply confirmed Dr M J rdle's view that the main cause of the syndrome of paræsthesiæ is compression of the median nerve in carpal tunnel Thus the controversial issue as to her the condition was primarily vascular or neural ntly settled by incriminating a pressure ischæmia e nerve

hat carpal tunnel narrowing is not the complete anation is accepted by the *Middlesex Hospital* ers for they state that in many cases the tunnel allow the passage of a raspatory Further not all of Russell Brain's syndrome suffer from the typical urnal attacks which characterise acroparæsthesiæ ccessive work with the hands, except in those cases an anatomical abnormality at the wrist appears e an invariable ætiological factor There remain wer features which still require explanation—in cular the age and sex distribution which is so ing Dr Kremer suggests that water retention may factor in precipitating the condition in pregnancy actation

ave been impressed that endocrinological disturbance lly played a part in this syndrome and have sought to ain this by fluid retention due to endocrine imbalance interesting how frequently slight ankle œdema at swelling of the fingers on waking and slight ions into the synovial spaces occur in pregnant and pausal women who suffer from this syndrome plete relief from the nocturnal attacks can frequently tained by treatment with salt restriction ammonium ide and mersalyl The fact that the acroparæs syndrome is not a symptom of the common œdematous states of cardiac and renal disease would appear to dispose of this hypothesis These conditions, however impose physical limitations which prevent the overwork that seems essential in the causation of the syndrome Fluid retention associated with endocrine imbalance may be the missing link in the pathogenesis of this interesting condition

Newmarket General Hospital R. ARDEN JONES

EXERCISE TESTS DURING HEXAMETHONIUM TREATMENT

SIR,—*Dr Ronnov-Jessen in his interesting article* last week drew attention to an unusual effect of exercise on the blood pressure of patients under the influence of hexamethonium Using this drug for the treatment of hypertension we also have found patients in whom the blood pressure falls on exercise One of us (P B S F) described this effect in a paper read to the British Cardiac Society in May of this year and a more detailed investiga tion on the variations of blood pressure during exercise and their control by hexamethonium is in the press.

In our patients who showed a fall in blood pressure on exercise, symptoms due to postural hypotension did not occur on walking if they were not present when the patients were standing still These patients were unusual in that they could not "walk off their faintness" *but their symptoms of hypotension were quickly relieved* by lying down

TUBERCULOSIS

SIR,—Professor Francis (Sept 26) justly takes me to task for assuming that the tubercle bacillus is ubiquitous and that tuberculosis cannot be conquered by physical eradication of the organism itself He points to the success of the campaign to eradicate tuberculosis in cattle

I am convinced. I agree that if we followed the same policy as in the case of cattle we could in time eradicate the tubercle bacillus from humans. This would mean that we would *slaughter all human infective cases* segregate in sanatoria and concentration camps &c the 30-odd million of reactors, and isolate for six months all persons coming into this country by sea or air submitting them to intradermal tuberculin tests and sending home or slaughtering the positive reactors Professor Francis I feel however would agree with me that such a policy would not be without its difficulties

I agree with him most heartily when he implies that the campaign for the eradication of bovine tuberculosis in this country is proceeding so slowly that the great majority of people do not realise that anything is happening This is only too true. He is mistaken, however when he includes me amongst this great majority In actual fact the knowledge has impinged upon my consciousness and I have referred to it in some detail elsewhere. This campaign for tubercle free herds dynastic rather than dynamic has already meandered through four reigns, and at the present rate of progress will take another thirty four years. In view of the fact that the United States succeeded in abolishing bovine tuberculosis in a period of twenty three years and Denmark in sixteen years, one can only compare the *pace* of the British campaign to that of an elderly snail with arthrodesed joints This excessively slow pace continues in spite of the brilliant work, enthusiasm and energy of the veterinary profession to whom the delay must be as exasperating as it is to public health doctors

Professor Francis accuses us of complacency because we accept the ubiquity of the tubercle bacillus in humans and points to the results of chemotherapy and B C G *vaccination but is he not confusing the eradication of* tuberculosis with the eradication of the tubercle bacillus ?

---

[1] *Lancet* 1938 ii, 241

Many of the most eminent chest physicians in this country have recently expressed great uneasiness with regard to the results of treatment by the new antibiotics, and very many of them believe that the result of modern chemotherapy is to achieve a partial cure of the patient while failing in many cases to render him non-infective The seriousness of such a state of affairs cannot be exaggerated

As regards B C G vaccination, surely Professor Francis would not seriously contend that it is a method of eradicating the tubercle bacillus ! The persons to whom B C G vaccination is given do not harbour any tubercle bacilli , on the contrary B C G vaccination actually injects these organisms into their bodies in a living condition and therefore *increases* the incidence of the bacilli in the community

Professor Francis begins his letter to you, Sir, by disputing that good housing and a good standard of living would eradicate the disease , but a couple of columns of his own letter have converted him somewhat, for he ends by admitting that " the rational application of hygienic methods will lead to the eventual eradication of tubercle bacilli from large sections of the population " Quite so !

Smethwick HUGH PAUL

SIR,—With diffidence I differ from Professor Francis Undoubtedly the principle of eliminating all infectious—and all potentially infectious—animals from the herd has proved 100% successful in eradicating bovine tuberculosis I would, however, underline Professor Francis's admission that " cattle can obviously be handled much more easily than men " Furthermore, though clinically and pathologically " tuberculosis in cattle resembles tuberculosis in man as closely as any other two diseases," it is questionable whether, from the epidemiological point of view, tuberculosis in cattle is equally comparable to the " white plague " in man All the evidence suggests that, in all civilised communities in which it has been epidemic for centuries, tuberculosis —not unlike syphilis—is gradually changing in character Generally speaking, it is no longer the deadly disease it used to be 50 or even 20 years ago I believe it is generally accepted that whenever tubercle bacilli invade " virgin soil," the ravages of the disease are infinitely greater than in a population which, as a whole, has over many generations acquired a high level of immunity, and where in the course of time more and more of the most susceptible and defenceless strains have died out This slow, but steady process of relative immunisation—always interfered with by major and prolonged disasters such as war—is essentially bound up with the ubiquity of the tubercle bacillus and has been bought at a high price But whereas in 1947 the death rate in this country was still over 50 per 100,000, it has since then sharply dropped to less than half that figure I do not know how far we may regard ourselves as responsible for this statistical trend, which is not matched by a similar reduction of the incidence rate We can hardly tell how far better housing, improved food and living standards, our advanced methods of earlier diagnosis and more effective treatment, or epidemiological factors (such as the survival of the fittest after the elimination of the unfittest) or psychological and other factors not yet clearly recognised, have played, and are still playing, a part in this startling process

But so far as our efforts to control the spread and the course of tuberculosis is concerned, this is a different proposition from trying to banish from our shores a virtually ubiquitous and mostly quite harmless germ May I repeat a warning which Professor Selter of Königsberg sounded many years ago ? He predicted that if it were possible to eradicate the tubercle bacillus from our population, we should sooner or later have to fa[illegible] consequences of breeding a race completely defenceless against this infection If Robert Koch's could be fulfilled a time might come when the population of Europe and America would be as t prey to the onslaught of tubercle bacilli as ar Eskimoes or the Negroes of Africa

Meanwhile the life long isolation of all infe sufferers and possible carriers (even if we knew all) is not a practical proposition, and we must be c with such " rational applications of hygienic combined with suitable propaganda, as the mea personnel at our disposal allow Nor is Ehrlich's th *magna sterilisans* in sight So it does not look as if known rational method of prevention will in any fo able future "lead to the eventual eradicatio tubercle bacilli from large sections of the popula

Dubos and Dubos, in their excellent book quote Professor Francis, say

> " It is certain that the disease will not be eradica vaccination, and it is likely that tuberculosis will a grave problem even in unvaccinated popula economic difficulties and social disturbances interfere with general well being But if peace a hope flourishes again in the hearts of men, tuber will recede as it has always done, spontaneously life has become easier and happier And then it little difference whether vaccination, or merely bette brighter lodgings, cleaner environment and heart have been responsible for the control of tuber

Holywood Hall Hospital,
Walsingham, co Durham E G W HOFF

PREMENSTRUAL TENSION

SIR,—Mr Albert Davis (Sept 26) is right Pre tension (or, as Dr Dalton and I preferred to call paper you were kind enough to notice, the p syndrome) is not uncommon 30% to 40% of wo it in a mild form In our paper we dealt only with cases, but with no special effort Dr Dalton was collect 52 cases out of a panel of 5000 patients edly many more could be found by an search

But I cannot agree with Mr Davis about pro Has he tried it in adequate dosage ? Very few p are relieved by a dose smaller than 10 mg a day for days in each menstrual cycle, but if doses of this are administered 90% are relieved I have found not only in the relatively small series which Dr D and I described, but in a much larger series of cases omitted because my records were insuffi detailed, and later cases treated since the paper finished On the contrary, ethisterone, even in d of 50 mg a day, relieves only 65% The Mr Davis's second paragraph (in which he says that about half the patients are relieved by p makes me wonder whether he " lumped together results of the two treatments

In an experience of some hundreds of patients with ethisterone, I can only remember one who from nausea One is bound to agree that the occ disruption of menstrual irregularity is tiresome How this rarely occurs when the treatment is by intra progesterone or oral ethisterone It is a real obj to treatment by progesterone implants, convenient th these are in many respects

As we said in our paper, androgenic treatment successful, but in doses small enough to be safe virilising effects it is less often successful than p one, and it has no advantages I have not yet enough patients with methylandrostenediol to c its effects with those of progesterone or methyl terone, but I suspect that they will be equal to th the latter and therefore inferior, except in very expensive doses, to those of the former It seems slightly more reasonable to treat patients with a h natural to their sex, especially if, as both Mr Dav

spect the cause of the bother is a relative deficiency
rogesterone Dr Joan Malleson in her interesting
r published in your issue of July 15, is also of the
ion that the premenstrual syndrome is due to an
lance between the two ovarian hormones Like
Davis and myself she has had success with both
terone and testosterone though her dosage of the
er was very low and of the latter perhaps somewhat
In some cases she has had success by using an
ogen in the immediately post-menstrual fortnight
observation difficult to explain on the hypothesis
h we have advanced

ndon, W 1 RAYMOND GREENE.

PREVENTION OF POLIOMYELITIS

R,—It has been pointed out to me that in 1939
net and Lush[1] found in Melbourne that there was
elation between susceptibility to clinical poliomyelitis
absence of antibody to herpes simplex although
932 Weyer[2] had found in New York that there was
a relation In view of the well known local vari
ty of viruses there is a case for reinvestigation
I still feel that, as suggested in my letter last week,
tural history survey of the virus diseases of poliomye
patients would be well worth while

ckley Rye, Sussex. C G LEAROYD

TUBERCULOUS MENINGITIS

R,—The article last week by Dr Anderson and his
agues and your leader prompt me to send a brief
rd of the following case,

girl aged 1 year 9 months was admitted on June 11
with symptoms and signs of meningitis. Findings in the
rospinal fluid (C.S.F) confirmed the diagnosis tubercle
li were found on direct smear and by Löwenstein culture
e patient was treated with streptomycin (50 mg intra-
ally daily for five weeks followed by the same dose on
nate days for three weeks) Intramuscular streptomycin
mg daily was also given for four months
e patient was discharged on Dec 30 1949 The last
imen of C.S.F contained 45 mg protein per 100 ml.,
e blood-cells 40 per c.mm and red blood-cells 543 per
n For a year she attended the outpatient department
her condition was very good
n Oct. 10 1951 almost two years later she was readmitted
symptoms and signs of meningitis It was then learned
she had been living with her grandmother who had open
onary tuberculosis. C.S.F contained 105 mg protein
100 ml 22 mg sugar per 100 ml 674 mg chlorides per
ml and 42 cells per c.mm ; no tubercle bacilli were
or cultured. Streptomycin (intramuscularly daily for three
ths and intrathecally on alternate days for eight weeks)
p-aminosalicylic acid were given.
e patient was allowed to go home on March 3 1952 after
temperature and general condition had been normal for
a month C.S.F on Feb 25 1952 contained 85 mg
ein per 100 ml and 13 cells per c.mm
e remained well for two months and then symptoms
red. On readmission her C.S.F showed signs of active
se and tubercle bacilli were grown on Löwenstein medium.
iazid 100 mg twice daily (and no other drug) was given by
th until January 1953 (incidentally with no side-effects)
C.S.F had almost returned to normal by Sept 25 1952
tein 50 sugar 50 cells 5) During the next three months
C.S.F became normal (protein 40 sugar 57 cells 4) She
attended the outpatient department since January this
and when seen in August she was very well

he following points are worth noting (a) recurrence
r nearly two years (b) effectiveness of isoniazid
(c) absence of side-effects after prolonged treatment
200 mg of this drug daily It would be interesting
know more about the mechanism of the recurrence
tivation of submeningeal foci or reinfection)

PYREXIA IN THE PUERPERIUM

SIR,—I should like to offer the following comments on the instructive and timely paper by Dr Calman and Dr Gibson (Sept 26)

The change in the definition of puerperal pyrexia as from Aug 1, 1951 (made no doubt, in all good faith to facilitate prompt isolation investigation and treatment of all infectious cases), had the immediate effect of trebling the number of cases notified each week in England and Wales Our experience suggests that this increase is made up almost entirely of cases of urinary tract infection, early mastitis (for the most part, simple engorgement of the breasts), respiratory infections and transient reactionary pyrexias which would not have fulfilled the requirement contained in the old definition which demanded that the temperature of 100·4°F should be maintained for 24 hours or recur during that period. I cannot think that an arbitrary level of pyrexia can ever provide a satisfactory basis for notification ; for example in postabortum cases it is not uncommon to encounter low grade infections, or even on occasion severe infections with spreading peritonitis, attributable to *Bacterium coli* and/or *Clostridium welchii* in which the temperature however prolonged never reaches the level of 100°F If the aim of notification is to ensure prompt isolation investigation and therapy is it any more necessary to define what is meant by puerperal pyrexia than to define what is meant by food poisoning or measles ? A common-sense deduction based on numerous factors in history and clinical findings is the final arbiter in either case If the aim of notification on the other hand, is to detect cases of true genital tract infection then the sooner the present system is abandoned the better

The bacteriological findings in the 141 cases of genital tract infection analysed by Calman and Gibson are remarkable not so much for the complete absence of hæmolytic streptococci of Lancefield group A as for the high incidence of anaerobic streptococci Routine anaerobic cultivation of all *cervical* swabs (I would emphasise the inadequacy of high vaginal swabs in seeking the true pathogen) and blood-cultures was instituted in the puerperal sepsis unit of this hospital by Prof Robert Cruickshank late in 1936 Since that time the average yearly incidence of anaerobic (both sporing and non sporing) organisms in postpartum puerperal sepsis has been 14 2% and the highest in any individual year 23 8% On the other hand, in post abortum puerperal sepsis the average yearly incidence of anaerobic organisms has been 35 4% and the highest in any individual year 57%

Our experience has suggested that organisms found on *cervical* culture in cases of genital tract infection can conveniently be divided into three groups :

(1) Those whose presence indicates active infection irrespective of the clinical findings Hæmolytic streptococci of Lancefield group A are the chief example but our experience with coagulase producing staphylococci would demand their inclusion as well.

(2) Those which though frequently harmless saprophytes are always potential pathogens, requiring only suitable conditions for proliferation—e.g traumatised tissue and necrotic retained products of conception Hæmolytic streptococci of Lancefield groups other than A, *Bact coli* enterococci and all anaerobic organisms are of this type

(3) Those organisms which are never pathogenic Coagulase-negative staphylococci and diphtheroids are the chief examples and their finding is tantamount to a negative culture

The present regrettable tendency to treat infections with antibiotics without carrying out the essential investigations is responsible for the large number of cases in which a satisfactory explanation of pyrexia is never obtained The increase in the number of available drugs and the rapidity with which organisms acquire resistance make it a matter of paramount importance that the infecting organism be identified, and its sensitivity reactions ascertained, if rational therapy is to be the rule

I notice that Calman and Gibson do not refer to the chapter on puerperal infections in *Modern Trends in Obstetrics and Gynæcology* This is probably the most comprehensive review of the subject in modern literature, and I think they might have found some useful information there

Royal Free Hospital,
North Western Branch,
London, N W 3

A MELVIN RAMSAY

SIR,—I have read with interest the article by Dr Calman and Dr Gibson but was surprised that no mention was made of a small gram-negative cocco bacillus which I have found fairly frequently in vaginal swabs from both pathological and normal cases Of the last 200 cultures from vaginal swabs taken at random, these organisms have grown in 20 instances (10%), most of these were from cases of puerperal pyrexia but some came from normal controls or cases of vaginal discharge in non-pregnant women

These organisms are best seen on the blood agar plates, after 48 hours' anaerobic culture, as minute pinpoint colonies resembling those of *Hæmophilus influenzæ* With a hand lens they can usually be found also on the aerobic blood agar plate They can be subcultured from the original anaerobic plate, and will grow aerobically on blood-agar, chocolate-agar, or serum-agar but not on plain nutrient agar The growth under anaerobic conditions is, however, always the more profuse Dr J Bamforth, investigating these organisms some years ago, found they grew well on Dorset's egg medium It is doubtful whether they are pathogenic, and as far as I am aware no one has yet given them a name, though their obvious preference for anaerobic conditions has suggested that they are related to the fusiformis (necrophorus) group, and the name "pseudo-necrophorus" has been used, but they would seem to me to be more suitably placed in the parahæmophilus group

I would be most interested to know how often Dr Calman and Dr Gibson found these organisms during their recent investigations, and what conclusions they reached about their origin and significance

Pembury Hospital, Kent.

W M R HENDERSON

SURGICAL TREATMENT OF VARICOSE VEINS

SIR,—Various views have been expressed in your columns regarding the stripping of varices, and I entirely agree with Mr Lang Stevenson (July 25), who states that this procedure will become the standard surgical treatment of the future In most cases the entire saphenous vein can be removed through two small incisions in groin and ankle without any hæmorrhage Unlike Dr Leighton (Oct 3), I prefer to remove the vein from below upwards, since this attenuates the branches joining the main trunk and minimises bleeding The patients are able to walk within 24 hours and suffer far less discomfort than when sclerosants are used With early exercise and a careful technique the risks of deep-vein thrombosis are negligible and end results are highly satisfactory

The stripping operation, however, does not absolve the surgeon from performing a careful resection of all tributaries at the sapheno femoral junction He must also at a later date be prepared to remove or inject any [illegible] which have been missed by stripping

A film which I made of this operation last demonstrates these points, and I am glad to that such wide support is being given to this pro

Those of us who operate on many cases must join with me in deprecating the "local li technique, which makes subsequent stripping difficult but often impossible

London, W 1

R ROWDEN F

EPIDEMIC VOMITING

SIR,—Interest in your annotation last week, with the recent article by Watson,[2] prompts me this brief account

During the past three months there have in this practice some half dozen *sporadic* cases type described They have been characterised very sudden onset of vomiting without health, by the intensity of the vomiting, 12–48 hours, and by the abrupt cessation other after effect than mild prostration for a two

The following case appeared to belong to group, but had in addition definite signs of nervous system involvement

The patient, a 47 year old potter's mould mak some unsteadiness and a tendency to stumble on quickly to the loft This lasted for a week, and at work, severe headache developed and he began The vomiting continued with great severity for and then ceased The headache, which was severe over the left temporal region, lasted a few On the 2nd day of the vomiting he complained vision was blurred, and he was found to have compl sided hemianopia, with loss of pupil light reflex light was shone from the right This lasted for and then he began to recover, recovery was con the end of a week There were no other abnormal signs in the central nervous system

These cases have coincided with an epid infective hepatitis in children, and the questio identity of the infecting virus in the two occurred to me In none of these cases, howe there jaundice or palpable liver or spleen, and t pictures were quite different I have assumed that the two conditions were separate entities.

Obituary

RALPH HENRY CROWLEY

M.D Lond, F R.C.P

r Ralph Crowley, whose death we announced last k, was one of the small team who in the first quarter his century planned and created our school health ice; *and it was fortunate for the service that in* e early years the post of senior medical officer at the rd of Education was occupied by someone with such rong bias towards preventive medicine

rowley was born in 1869, the son of the late Alfred wley of Croydon He was educated at Brighton Grammar School and St Oliver's Mount School Scarborough and he studied medicine at St Bartholomew's Hospital and in Berlin After qualifying in 1893 he held house-appointments at Barts and at the Hospital for Sick Children Great Ormond Street, before he joined the staff of the Bradford education authority as school medical officer He was also appointed to the staff of the Bradford Royal Infirmary Meanwhile he had taken his M.D in 1895 and his M.R.C.P three years later

[Elliott and Fry

In 1909 he joined the staff of the Board of Education, about two s after the establishment of its medical branch His agues were the late Sir George Newman the Dr Alfred Eichholz, and Dr (now Dame) Janet pbell. Before the 1907 Education (Administrative isions) Act, which placed a duty on local education orities to provide for the medical inspection of lren at school a few of the more important and ressive authorities, such as Bradford had appointed ol medical officers but for most the idea of a medical ice allied to the educational service was new wley's clinical experience and knowledge was invalu to his colleagues at the board for he was able lothe the bones of administration which in those y days was the main preoccupation of the medical ch with living tissue Sir George Newman was *inted chief medical officer of the Ministry of Health* Board of Education in 1919 and in 1925 Crowley me his *senior medical officer in charge of the medical* of the Board of Education.

lways open to new ideas, Crowley did much to ulate investigation and research both by doctors in wn department and by school medical officers working e field Investigations into the eyesight of children ropometric standards and the assessment of physical iency were some of the inquiries initiated by him and ied out by his own medical officers in collaboration those of local education authorities. Of the many mittees with which he was associated during his ial career perhaps the most important was the rdepartmental Committee on Mental Deficiency set n 1924 by the Board of Control and the Board of cation. Dame Ellen Pinsent at the former board and wley at the latter were the chief sponsors of this mittee and of the five years investigation it under-

Crowley had been uneasy in his mind for years t the certification as mental defectives under the cation Act of 1914 of large numbers of children who e merely backward educationally The committee not need much suasion to recommend that this ification should be restricted to children whose mental *ition or behaviour rendered them suitable to be* t with under the Mental Deficiency Acts but it was wley's forceful advocacy that made doctors teachers, members of the general public realise the importance his recommendation He was also chairman of the mittee of Inquiry into Problems relating to Partially sighted Children which issued its report shortly before his retirement in 1934

J E U, one of his colleagues at the Board of Education, writes:

> His vitality and enthusiasm tempered by a keen sense of what was practicable made him an inspired adviser on the development of the school medical services and on the education and well being of children handicapped by physical *and mental disabilities His sound educational philosophy* enabled him to appreciate the interdependence of medical and educational issues and assured him a sympathetic consideration of his views from his educational colleagues. Teachers felt encouraged and stimulated after his visit to a special school Even backward authorities and obdurate directors of education were overcome by his transparent sincerity and persuasive power He had an intense concern for the mental as well as the physical well being of children Child guidance and the psychological problems of the child suffering from mental ill health made a particular appeal to him. In 1920 he visited the United States to learn at first hand what was being done there for the mental welfare of school-children. He returned deeply impressed with the ideals which lay behind the child guidance service and its great possibilities for good He at once saw the medical-educational implications of this comparatively new service and threw his accustomed energy and enthusiasm into stimulating local education authorities and voluntary bodies to establish new child guidance clinics or to extend existing arrangements He probably did more than anyone to encourage the inclusion of a child guidance service in the educational programmes of this country Those of us who worked with Crowley will remember him as an inspiring leader and a man imbued with the deepest sense of humanity and idealism.

Many, as I am, writes E O L. are indebted to Crowley for opening their eyes to the importance and wide scope of social medicine

> He maintained that the doctor cannot fulfil his more specific function of treating bodily diseases, if he is indifferent to the patient's environmental conditions and his mental and moral welfare Adopting this standpoint it was not surprising that Crowley became one of the pioneers of the garden cities at Letchworth and Welwyn He was a man dominated by a passion to serve his fellow men He was a Quaker—first, last and at all times, in all things, and in all circumstances. His was the most consistent personality I have known There was *no discrepancy* between his ideals and his acts. *He would* have none of the casuistry of such maxims as the end justifies the means. Wittingly or unwittingly he was a Kantian— ought implies can, and if the end sought is right Crowley maintained that it can and must be achieved by right means
>
> He was a man with infectious enthusiasm, and in this he remained almost boyish to the end A stranger might receive the impression—a completely wrong one—that he was a man of impulse with evanescent emotions He would not give rein to his enthusiasm until he had considered carefully and critically any cause he championed *He was a great lover of* Nature and when he was moved by some fine scenery his enthusiasm became ecstasy One of my most treasured memories is a long fine summer evening we spent together in the gardens adjacent to the Portmeirion Hotel in North Wales His knowledge of flowers shrubs and trees was encyclopædic, but what made the deepest impression upon me was his delight almost childlike in its spontaneity It was fitting that Crowley when he set aside the heavy responsibilities of his post should retire to his garden It is hoped that he has left us some record of his reflections in this garden during the last fifteen years.

Dr Crowley married in 1902, Miss Muriel Priestman of Bradford and there are two daughters of the marriage

THOMAS ARCHIBALD MALLOCH

M.D McGill, F R.C.P

Archibald Malloch librarian of the New York Academy of Medicine, will be remembered by many colleagues in this country who knew him during the years he spent in Oxford and London as one of the editors of the annotated catalogue of Osler's library

He was born in 1887 at Hamilton, Ontario *one of the* three sons of Dr A. E Malloch, who was one of Lister's house-surgeons at Glasgow and a life-long friend of Sir William Osler Qualifying at McGill in 1913 he served with distinction at Depage's Belgian war hospital and later at the No 3 Canadian Hospital in France during the first world war, he took the M R C P Lond in 1919

His interests lay more in the scholarship than the practice of medicine, and his first essay in medical history, written at Osler's instigation, was the delightful book *Finch and Baines, a Seventeenth Century Friendship*, beautifully produced by the Cambridge Press in 1917, while he was serving in France His appointment in 1925 as librarian of the New York Academy of Medicine was fortunate for himself and for the academy He promoted the growth and activity of his department till it has become one of the largest and most up-to date medical libraries in the world, at the same time he made its great resources readily accessible to all serious workers He took an active part in the affairs of the library profession, and did not neglect the historical studies which were so near his heart His writings were not frequent, but they display his personal charm, while the famous rare-book collection at the New York academy owes much to his guidance In 1930 he was elected to the fellowship of the Royal College of Physicians of London, and in 1939 he was appointed FitzPatrick lecturer The outbreak of war and his own ill health prevented him from delivering the lectures, but they were published by the college in 1946 They are a learned and entertaining survey of *Medical Interchange between the British Isles and America before 1801*

He retired from his librarianship in 1949 after a coronary thrombosis He died on Sept 19 at White Plains, New York

HUGH HERCUS CAVENDISH FULLER

M D Edin

Dr H H Cavendish Fuller, chief medical officer to the Railway Executive, died at the age of 66 in St Mary's Hospital on Sept 30

He was educated at Bishop's Stortford College and at Edinburgh University, where he graduated M B in 1912 On the outbreak of war in 1914 he was attached to the Royal West Kent Regiment and he served in France with the rank of captain In 1916 he was invalided home and later he was appointed officer-in-charge of the Princess Marie Louise Military Hospital at Bermondsey

On his return to civilian life in 1917 he became medical officer of Malvern College and later he also practised privately in Malvern He was also honorary consulting surgeon to the Great Malvern Hospital and medical referee to the Ministry of Pensions for the Malvern area

In 1930 he became assistant medical officer to the Great Western Railway at its Paddington headquarters, and he was promoted to chief medical officer two years later During the late war he was in medical charge of first-aid at Paddington, and he was also medical officer to the Great Western Railway zone, to the 38th battalion of the Home Guard, and to the Kensington Sea Cadets He was vice-president of the Union Internationale des Services Médicaux des Chemins de Fer Besides his railway work he held the appointment of medical officer to the Channel Islands Airways, chief clinical assistant at the National Hospital for Diseases of the Heart, and clinical assistant at the British Red Cross Clinic for Rheumatism, Peto Place

C T N writes "Those who worked with Dr Cavendish Fuller came to admire his kindness, tact, and honesty of purpose By his services to railway medicine he has shown the way to many advances During his long illness he showed fortitude and courage, and concern for the feelings of others His loss will be deeply felt throughout the British Railways the administrations of foreign railways, and his broad circle of friends"

During his life as general practitioner, school medical officer, and in industrial medicine Cavendish Fuller made many contacts and crowds of friends outside his specialty One of them, A D W, writes

"Cavendish Fuller's desire to solve problems in an amicable way sometimes gave the impression that he was timid, but his solution was generally the best one possible and by quiet methods he generally secured his end. His good humour and his kindness of heart were unfailing, and no trouble and no distance would stop him from making a good natured gesture to a friend in trouble To the end he spared the feelings of [illegible]ound him No trace of quer [illegible] ss or awkward question revealed itself, so that one came to the
perhaps the seriousness of his illness had been conce
him The discovery of an entry in his diary man
before showed that it was he, and not his advisers,
successfully playing a part"

Dr Cavendish Fuller married Miss Janet
1917, and she survives him with one daughter

WINIFRED LINTON

S R N, Hon F C.S P

Miss Linton, head of the department for
exercises at the Brompton Hospital for Diseases
Chest, died on Sept 7 She was trained as a
St Bartholomew's Hospital, and served with the
in the Dardanelles in the first world war After
home she took up physiotherapy, and began her
the Brompton Hospital, first with J E H. Rob
later with Tudor Edwards

G M writes "Miss Linton was the most modest
regardless of women, but she was a genius. If the d
of a patient were explained to her, she would devise
and postural procedures which would reduce the dis
a minimum, and she would gain the confidence
coöperation of patients of all ages and of every rank
She trained many other physiotherapists, and
have become heads of departments in hospitals
abroad She was a woman of small stature and of no
distinction in appearance, but her zest and her
devotion to the relief of her patient carried instant
and made her respected and beloved She had a
sense of humour and she was a dear"

Notes and News

EDICAL FILMS AT INTERNATIONAL CONGRESS

URING the 7th International Congress of Scientific Films this year in London, 73 medical films from nineteen ons were shown Practically every aspect of medicine represented but the emphasis seemed to be on the use lm in health education and the popularisation of medical ues in different parts of the world. Films of this type ided the production and investigation of antibiotics gium) an appeal for blood-donors (Denmark) dental ene (Great Britain) nutrition (Italy) the prevention of id worm infection (Japan) the importance of vaccination eria) sex education (Sweden) anti tetanus inoculation guay) the work of a local midwife in Georgia (U.S.A.) recent advances (U.S.S.R.) Though these films were le for public distribution in their own countries, many of n were judged unsuitable for public exhibition in Great ain

f the specialised films *Manganism* (Morocco) deserves ial mention, not only because this industrial disease is arely seen in this country but because of the quality of exposition and photography Dr H Rohracher had ght from Austria a series of interesting psychological les, including a fascinating comparison of adult uniovular binovular twins filmed together while they performed lar tasks such as going up steps and shaving and rienced similar emotions as when watching a film of an operation. From Switzerland came a survey film on the of *p* aminosalicylic acid in the treatment of tuberculosis, from Germany a study of infants feeding at the breast, a bottle and with a spoon Prof J Calabek had ght from Czechoslovakia his detailed demonstration of r anaesthesia, and from France came a very complete y of rheumatism. Dr J Nauta (Netherlands) showed *excellent examples of cineradiology as did Britain's* pioneer in this field Dr Russell Reynolds. From nce also Prof A. Policard showed his new time-lapse phase rast cinemicrography film on pneumoconioses and Dr Bessis sent some electron microscope shots of normal pathological red blood-cells.

would seem that the enthusiasm for filming operations n the decline for few were submitted to this year's gress. Of the dozen medical film programmes arranged two contained films of surgical operations. In such s the interpolation of diagrams during the operation as lms from Italy and the Netherlands, makes them more ul than those which are simply visual records of operations ch as a film on a cholecystectomy which was not improved he addition of the third dimension Great Britain was, haps, more ruthless than some in selecting films to be nitted to the congress, with the result that the films wn were of a very high standard Special mention should made of *The Prevention of Cross Infection—Airborne ction* (Ministry of Health) *The Human Blood Fluke* llcome Film Unit) and *Venepuncture* and *Marrow Puncture* I Film Unit) A few examples of the scientific films during the congress were shown on a B B C television gramme Of the ten films included, four were medical n interesting reflection on the high quality of the medical s.

NEW CHESHIRE RADIOLOGY DEPARTMENT

n Oct. 2 Dr Peter Kerley president of the Faculty of liologists, opened a new and enlarged radiological artment at Clatterbridge Hospital Bebington.

he new unit is self-contained but has been planned to good circulation from the wards and direct access to the oining operating theatre suite There are three X ray ms: the general room has a 4 valve high power unit for eral and fluoroscopic work, and a cranial radiography paratus; the fluoroscopic room has a 4 valve high power for gastro intestinal chest and heart examinations; the genito urinary room has a 4 valve high power unit h urological table Electrically operated pass hatches access from each of the X ray rooms to the central kroom, and a drying room gives alternative darkroom ulation from one of the X ray rooms

he consultant staff of the department are Dr R J tting Dr J P McLaughlin, and Dr A G McCarey

University of Durham

Mr A G R Lowdon has been appointed to the chair of surgery in the Newcastle division (medical school) of the university He will also hold the post of surgeon at the Royal Victoria Infirmary Newcastle upon Tyne

Mr Lowdon is a graduate in arts and medicine of Edinburgh University He took his M.B. with honours in 1936 when he was the Ettles scholar of his year He was also awarded a Vans Dunlop scholarship in surgery and pathology He was a senior president of the Royal Medical Society After holding house appointments at the Edinburgh Royal Infirmary and the Royal Hospital for Sick Children he took the F.R.C.S.E. in 1939 On the outbreak of war he joined the R.A.M.C with a territorial commission Later with the rank of lieut -colonel he was in charge of the surgical side of a hospital in France, and in the *Edinburgh Medical Journal* he described a series of abdominal wounds treated by laparotomy On his return to civilian life he was appointed assistant surgeon to the Edinburgh Royal Infirmary and lecturer in surgery to the university He has lately published in our columns papers on the treatment of acute perforated peptic ulcer by partial gastrectomy and on the deflation of the distended bowel at operation

Royal College of Surgeons of England

Sir Ernest Finch will deliver the Thomas Vicary lecture at 5 P.M. on Thursday Oct 29 at the college Lincoln's Inn Fields London, W C 2 The title of his lecture is The Forerunner

Royal College of Physicians of Ireland

The following were successful in the D.P.M. examination held in September

L L Shenken R E Jenkins T H Bewley H M Flanagan D D Ellis, J A Kelleher

Courses for General Practitioners at Cambridge

During 1953–54 a series of one-day symposia for general practitioners will be held on Saturdays at Addenbrooke's Hospital, Cambridge Each symposium will consist of three to five lecture-discussions and demonstrations of clinical cases or modern methods

The following programme has been arranged tuberculosis and other diseases of the chest (Oct. 24) disorders of the blood (Nov 14) dermatology (Dec. 12) obstetrics and gynaecology (Jan. 9) infectious diseases (Feb. 6) cardiovascular diseases (March 6) orthopaedics treatment of injuries, and physical medicine (April 3), cancer (May 1) paediatrics (May 29) nervous diseases (June 26) diseases of the ear nose and throat, diseases of the eye (July 24) Further information may be obtained from the secretary of the Medical School Tennis Court Road, Cambridge

Medical Society for the Care of the Elderly

A meeting of this society will be held on Thursday and Friday Oct 22 and 23 at the City Hospital Nottingham Further particulars may be had from the secretary Dr H. P Jameson, 150 Harley Street, London W 1

National Marriage Guidance Council

Dr Noel Harris is to give the Gillies lecture at the rooms of the Royal Society Burlington House Piccadilly London W 1 at 6 P.M. on Wednesday Oct 28 The title of his address is Ourselves as Others See Us.

London Medical Exhibition

Lord Horder will open this exhibition at the new hall of the Royal Horticultural Society Greycoat Street S W 1 on Nov 16 at 11 30 A.M. The exhibition will be open daily from 11 A.M. to 6 30 P.M. till Nov 20

Middlesex Hospital Medical School

At this school's annual dinner on Oct 2 Mr C P Wilson the chairman was able to give a favourable account of the past year The Queen has bestowed her patronage on the hospital thus sustaining a tradition that has been uninterrupted for more than a hundred and thirty years. The Middlesex has won the inter hospitals competition for the best kept garden; the nurses have won the inter-hospitals tennis cup for the third year running (this is the second time that they have won it outright) and the students have won the inter hospitals cricket cup The Chairman spoke with awe of the high standard of the students work and looked forward to the time when they would hold a refresher course for consultants The Chairman was proposing The Hospital and Medical School and Sir Harold Boldero the dean, and Dr C. G H Newman (senior Broderip scholar) responded Sir Harold referred with pleasure to the new Institute of Clinical Research The board of governors decided that they would willingly spend much of the endowment fund on research and a house to the north of the hospital was purchased, to accommodate the institute which would be under the directorship of Prof Alan Kekwick Finally Prof B W Windeyer proposed The Chairman

Nuffield Gerontological Research Fellowships

The Foundation has awarded a professorial research fellowship in gerontology to *Dr P L Krohn, reader in* endocrinology in the University of Birmingham, and a fellowship of less senior status to Mr D A Hall, PH D, lecturer in medical biochemistry in the University of Leeds

Society of Chemical Industry

At a meeting of the microbiology group to be held on Thursday, Oct 15, at 6 15 P M at 11, Chandos Street, London, W 1, Mr E F Gale, SC D, will speak on Actions of Antibiotics in the Bacterial Cell

West End Hospital for Nervous Diseases

Clinical demonstrations will be given on Tuesdays at 5 30 P M from Oct 13 to Dec 15, in the outpatient department of this hospital (40, Marylebone Lane, W 1) All demonstrations are free, and are open to doctors and senior medical students

National Association for Mental Health

This association is holding an inter clinic conference for professional members of child guidance staffs, on Nov 21, at the Y W C A, Great Russell Street, London, W C 1 Further details can be had from the conference secretary of the association, 39, Queen Anne Street, W 1

Link between General Practitioner and Hospital

The *News Chronicle* (Oct 5) reports that at the General Hospital, Birmingham, general practitioners are to be welcomed in the wards on Tuesdays and Fridays by the registrars, house-officers, and ward sisters They will be shown the case notes of patients they recommended for admission, and told about treatment and progress.

CHANGE AND PERMANENCE IN EDUCATION FOR MEDICINE*

Sir Harold Himsworth
.C B M.D Lond., LL.D Glasg F.R C.P Q H P
SECRETARY TO THE MEDICAL RESEARCH COUNCIL

ERE are perhaps few things upon which all men are rood as that the problems which beset them today s in difficulty those which confronted any previous ation It is maintained that never has knowledge so complex nor the pace of life so insistent that r has it been so difficult to escape from the needs of noment and to take thought on those larger con ations which allow men to appreciate the trend of ts and the measures by which they might be con d These are comforting thoughts but they are nique To every generation contemporary problems f unsurpassed difficulty—*c'est son métier* and like very generation seeks to insure against failure by gerating this.

drag oneself away from the reassurance of present no in order to restore one's sense of perspective is ps the most arduous task which men may essay It is only on the basis of such attempts that we can e to manageable form the welter of detail which tens ever to submerge us. I take it that it is to this that the centres of thought in our civilisation—the ersities—have created occasions like the present in h they license us to step back from the canvas and y and get a broader impression of at least some of the particular picture upon which we are engaged mit at once that I have not the temerity to think lf equipped for any comprehensive consideration of ical training so let us select three problems and with them broadly They are I am afraid widely rated parts of the whole picture, so what I have to s bound to be disjointed But they have this feature mmon—each involves an essential consideration in of the major problems of medicine The first concerns ical education the second, the teaching hospital the third, professional obligation

Purpose of the Curriculum

introductory address at any medical school could ibly be considered adequate if it did not touch on the lem of the undergraduate curriculum Today it is icularly relevant Perhaps at no other time in the ry of medicine has so much concentrated effort been ted to diagnosing its ills Indeed there has just been nternational conference in London on the matter; there was no lack of controversy Let us however with something that is agreed

think that one can fairly say that every professor agreement on one point—that the course is being burdened with detail by other professors There is h truth in this and also in the further contention that *this constant preoccupation in acquiring detailed* wledge which militates against the development of student's capacity for thought. But despite this ral agreement every year sees something more added his curriculum and we seem as far as ever from overing the criterion for deciding what shall and what l not be included in the undergraduate course Now state of affairs has all the features of one of those using situations which arises when we have failed to back from the picture and answer clearly the tion What are we trying to do?

ell what are we trying to do in the undergraduate se? Are we trying to produce an Admirable Crichton who, alone in an isolated community is perfectly capable of dealing with every variety of ill to which man is heir or are we trying to give a basic education on which a man who has been taught to think can develop his special interests? Put like this the first alternative appears a *reductio ad absurdum* Yet if one examines the medical curriculum in this country it is difficult to avoid the impression that it has drifted into this absurdity The dilemma seems to me to have arisen from a failure to face the full implications of two facts First that the capacity of the human mind is limited so that men must specialise or at least have a special interest within their profession Second that general practice is as much a specialty requiring postgraduate training as any other branch of the profession

Until very recently all attempts to face the implications of these two facts foundered upon the objection that in this country a man was assumed to be competent to practise medicine independently from the moment he passed his final qualifying examination But that situation is at last changing This year the system of compulsory house appointments was introduced and now after qualification a man must have a year's practical experience before his name can be included in the Medical Register I was one of the many persons concerned in urging this requirement and one of the strongest considerations which weighed with me was that besides ensuring that the necessary modicum of experience was acquired it would free the teachers in our medical faculties from a stultifying preoccupation with practical requirements Until some such provision for postgraduate experience was made such practical requirements imposed an *insuperable obstacle to reform* of the undergraduate curriculum But the way is now clearing Undergraduate medical education provided it is remembered that general practice is also a specialty need no longer aim at producing ready made Admirable Crichtons Like any other faculty in the university the medical can now devise a course of education based on representative rather than comprehensive experience Only thus can it be liberated to become educative in the true sense that of equipping men to educate themselves

But *this reform depends upon confidence* that the appointments held in the first year after graduation are such as will adequately supplement the training given in the undergraduate period It will therefore be necessary to ensure that the nature of these appointments and the arrangements for continuing training in the hospitals where they are held, are suitable for this purpose We might well be able to learn some useful lessons from American experience in this respect

Purpose of the Teaching Hospital

Now one of the difficulties in the organisation of medical training—at least in the clinical years—is that it has to be adjusted to the structure of the health services whose facilities it requires That brings me to my second point the place of the teaching hospital in the health services of this country

Few of us would cavil at the statement that the teaching hospitals of the country are *national* assets but I wonder if the implications of this statement have been fully realised The National Health Service Act lays on the boards of governors the duty of providing the *facilities necessary for medical education and research* but does not specify the priority that should be accorded to this among their other manifold responsibilities That there is some divergence of opinion on this point is evident It may therefore interest you to know the view of one of the greatest and most successful administrators of a teaching hospital, Dr Nathaniel Faxon of the Massachusetts General Hospital in Boston He epitomised

---

ddress at the opening of the session 1953-54 at the Faculty of Medicine University of Birmingham, on Oct 3 his considered judgment on this matter in one sentence

> "The functions of a teaching hospital are first, to advance knowledge, second, to set an example of practice, and third, to train future doctors, they are not primarily to cater for local needs"

Stated in this forthright manner these opinions may seem a little startling, but, if one examines them, their inescapable logic impresses

Leaving aside, for the moment, the order of priorities he assigns to these different functions of a teaching hospital, I think that we should all agree that to advance knowledge, to set an example of practice, and to train doctors are, each and all, duties which a teaching hospital must undertake But none of them can be discharged in any high degree without special facilities special staff, and specially directed effort on the part of all concerned For medical education all are required Taken together, their demands on an institution are so exacting that they are unlikely to be met unless their full realisation is taken as the primary and deliberate aim of policy to which other claims must be regarded as secondary

But let us return to the first part of this statement and examine the priorities accorded to the different functions of the teaching hospital There is the same clear logic in the sequence given to these priorities How can one set a high example of practice if one is not advancing knowledge? How can one train future doctors if one is not setting such an example? The motive point is research Personally, I would go so far as to say that in the association of research with teaching we have the essence of the distinction between education and training And it must necessarily be so if the aim of education is to liberate a man to think for himself The crucial test of a man's understanding of a subject is his ability to advance it If a student does not see his teachers thinking effectively how can he learn to think for himself? It is only by living and working in an atmosphere imbued with the thirst for new knowledge that a student can acquire that critical receptivity and perception on which alone he can rely when, as so often happens in medicine, established knowledge fails him

Professional Obligations

And now I come to my third point—the professional obligations of medicine in a changing society

This is a large and complicated subject, but as in all such subjects the underlying principles are relatively simple They are simple because they are based upon permanent features of human society And they apply, not only to medicine, but to those other human activities which, in popular opinion, are distinguished as the professions If, therefore, we are to steer our way with confidence through the detailed perplexities of the present we must endeavour to grasp clearly the nature and significance of those principles which underly the concept of a profession

The idea of a profession is entirely a social concept Apart from society it has no meaning Essentially the concept implies the recognition by society that, if its needs are to be met in a particular respect, then the body of men undertaking this obligation must be given certain special considerations In effect a tacit social contract is implied obligation on the part of the professional man to use his best endeavours to meet the particular need of his society, obligation on the part of the society to accord to the professional man such status, authority, and privilege as shall be required for him to discharge his obligations Only in so far, and for so long, as this implicit contract is observed will the profession in question survive It is as well to be clear on this point, for it is the inherent weakness of all associations of men to t the bonds which unite them together into a ne and to forget the mundane and utilitarian requirements upon which their profession depends for its continued existence

But, if professions arise, and exist, to meet a society, what is it that society requires of them

First, it requires a special competence—the skill to meet, to an ever increasing extent, t called the particular profession into existence Law that requires competence in applying and preting the rules of conduct in the particular in the teaching profession it requires the acquis knowledge and the skill to impart it, in med implies competence to preserve health and to treat Unless society has the requisite degree of confid the technical competence of its professions th helpless And what is that degree? In the pre the standard of competence required to elicit confidence is never the ordinary The needs to b are too vital for confidence to survive the suspic the best has not been available It is this which the continued prosecution of research an essential in maintaining public confidence in our profess is this which makes the continued striving after lence, rather than mere competence, the professional endeavour

But all this might apply to any skilled human It is not this which has distinguished the profe the mind of the man in the street The efficient di of our technical obligations—essential though could never have won for us the trust—and I might still say the affection—with which the regards our own profession To find the explana this we must look deeper

The whole trend of human development is tow elaboration of closely integrated communities within the structure of such can men find that which permits them to develop those special ski obtain, for the community as a whole, a master natural environment far greater than could achieved by any individual living independently each step towards individual specialisation men more dependent upon, and subject to, and we are all, unfortunately, only too well men are essentially individualistic, each with desires, needs, and interest In this conflict individual and social interest lies the dilemma society To meet it men have created, and en systems, but, although these may suffice to giv modicum of confidence required to prevent soci integration, they cannot promote that increase upon which the development of society depends can come only from voluntary acts which confidence between men, and there is no more stimulus to this than that of a man, or a body voluntarily subordinating themselves to a stand social morality more exacting than that required community in general Such voluntary subordi is the hallmark of those vocations which are distinguished as the professions It is this which a for the special respect in which they are held privileges which they are accorded

More than two thousand years ago a code of c was laid down for the medical profession To th that the spirit of this code has been faithfully o by succeeding generations of medical men we attribute the public trust which we have inherited the original code was concerned only with the re of medical men to individuals under their care. medicine has acquired extensive relations with soc general Nevertheless the spirit of the Hippocrat is as relevant to medicine now as it was two th years ago And what is its essence? It can be one sentence *Act always so as to increase trust* the first and paramount law of social ethics. In relationship with individuals act so as to increase n your professional skill and your character as a In your research act so as to increase confidence in fic integrity In public relations act so as to se the confidence of society in your profession that criterion as a guide, whatever changes occur social context neither the individual nor his sion need fear the future

ION-EXCHANGE RESINS IN THE TREATMENT OF ANURIA

: prognosis of cases of anuria or of severe oliguria acute tubular necrosis has greatly improved since itroduction of the conservative régimes of Borst and Bull et al (1949) Previously such cases were fatal either from pulmonary œdema due to the istration of large intravenous infusions or from c arrest due to hyperkalæmia Pulmonary œdema cause of death has been virtually eliminated by n methods of therapy but cardiac arrest from kalæmia although delayed is still not unusual otassium levels in the plasma and extracellular ave been satisfactorily reduced by dialysis methods, ling the artificial kidney (Kolff 1947) peritoneal tion (Fine et al 1946) and intestinal perfusion f 1948) These methods have recently been reviewed acLean (1952) they have the disadvantages that l experience and apparatus are necessary the enance of the fluid balance is often difficult and ion may easily take place in the former two methods inal perfusion is relatively less effective and has cal difficulties, unless an isolated loop of the bowel pared surgically, but this is a severe operation for a ly ill patient.

much simpler but still effective method has been ibed by Elkinton et al (1950) who administered a xylic ion-exchange resin charged with ammonium oth orally and by retention enemata and obtained y satisfactory exchange for potassium ions, with nite fall of the serum potassium level

consider that a sulphonic resin charged with m has considerable theoretical advantages, because inge with this type of resin is more rapid, and m is more innocuous than ammonia in anuric nts. The ammonia is converted to urea in the liver vill therefore raise the already high blood urea level ldition acidosis which is almost invariable in these nts, is increased because a basic ion is exchanged ect for neutral urea Further evidence will be given that there is already present in the colonic contents many uræmic patients a high concentration of onia which will tend to diminish exchange with an onium resin. The small amount of sodium given up sodium resin is relatively harmless and does not ar to cause either œdema or hypertension A short t of a single patient treated with this type of resin een given by Bull (1952)

o describe here our experience with a sodium sul lc resin* in the treatment of five cases of anuria or re oliguria complicated by hyperkalæmia together relevant observations of the effect of the resin in a nal person on a low-electrolyte diet. All the cases of ia were from other hospitals, and therefore resin treatment was not given in some cases as early as we recommend in this paper

Methods

The resin used was of coarse grade and consisted of irregular particles of diameter 100–400 μ. The binding capacity of the resin was 3·4 m eq cation per g of resin. About 90% of this was sodium but 3% calcium and 7% ammonium ion was also present Since the resin was completely free from potassium the small proportion of cation other than sodium was of little if any importance It was administered both by mouth and by retention enema the dosage being 15 g three or four times daily by mouth and 30 g daily by enema. The resin was too coarse to be given by the narrow 'Polythene' intragastric tubes used for the administration of the fluid electrolyte free diet of Bull et al (1949) It had to be swallowed by the patient either with water or after being made into a paste with 'Golden Syrup' A resin of finer grade would be more easily given to uncoöperative patients but was not available at the time of this trial † The retention enemata were made up according to the following prescription and were easily given with the aid of a little pressure

Sodium sulphonic resin	30 g
Emulsion promulsin ‡	100 ml
Aqua dest	100 ml.

The cation content of the resin was estimated by washing out the resin from fæces with distilled water and elution of electrolytes with 2N HCl as described by Barker and Mackay (1951) Preliminary drying of the fæces was found to be unnecessary but the recovered resin was thoroughly dried in an oven at 103°C The more standard burning technique at 400–600°C was difficult with this type of resin since ashing was incomplete at temperatures below which cation may be lost by volatilisation The elution technique would be impossible if a fine grade resin were used Slightly less cation was recovered from resin after exchange in the gut This is due to the fact that divalent cations and potassium have a higher affinity for resin than sodium and were therefore eluted for analysis less completely Values for potassium exchange are therefore slightly underestimated throughout The following analytical methods were used: sodium and potassium flame photometer calcium method of Clark and Collip (1925); ammonia, nesslerisation magnesium method of Kunkel et al (1947)

During the administration of the resin the patients were given the diet of Bull et al (1949) which consists of 400 g of glucose and 100 ml of peanut-or olive oil made up to 1 litre with distilled water gum acacia being used to emulsify the oil If vomiting or diarrhœa became troublesome, the oil was reduced to 25 ml. If these symptoms persisted the intravenous régime of Bull (1952) was used This consists of the slow intravenous infusion of 1 litre of 40% glucose into the superior vena cava through a polythene tube introduced via an antecubital vein, nothing except small amounts of water being given by mouth Infusion into a large vein is necessary since this concentration of glucose rapidly causes thrombosis in smaller veins

In the normal person a modified Borst (1948) diet was used consisting of sucrose 150 g custard powder 100 g 'Casilan' 50 g (calcium caseinate) and butter 50 g made into a thin custard with 1500 ml of distilled water This diet contains only 7·5 m eq of potassium a day

Case records

Case 1.—This patient was transferred to Hammersmith Hospital on the fifth day of the oliguria She had been well until the thirty sixth week of her eleventh pregnancy when she developed severe abdominal pain and vaginal hæmorrhage She was delivered of a stillborn child, and the placenta had a large retroperitoneal clot typical of concealed accidental hæmorrhage Severe oliguria followed only a few ml of bloodstained urine being passed each day

Treatment—The patient was treated with the intragastric drip method for eleven days and then with the intravenous régime for a further nine days. The urine volume slowly increased to 600 ml daily but no more By the twelfth day of

---

nufactured by Bayer Products Ltd. This resin should not e confused with 'Katonium' resin which is charged with a ixture of 75% ammonium ion and 25% potassium and would e contra indicated in anuria.

† It is understood from the manufacturers that a fine grade and more highly purified form of the resin, with the proprietary name of 'Resonium-A' will shortly be available in adequate quantity

‡ Manufactured by Watford Chemical Company

the oliguria the serum potassium level had risen to 6 m eq per litre, and treatment with resin was started In five days the serum potassium level had fallen to 4 4 m eq per litre, 270 m eq of potassium having been eliminated by the resin and only 37 m eq in the urine The blood urea level slowly rose to 430 mg per 100 ml, and the patient died in coma on the 23rd day of the puerperium

Necropsy showed gross bilateral renal cortical necrosis (fig 1) recovery being impossible owing to the widespread and irreversible renal damage

Case 2.—This patient was transferred to Hammersmith Hospital on the fifth day of the oliguria She had a retained placenta after the delivery of her first child Manual removal caused considerable shock and hæmorrhage, which was treated by infusion of dextran Subsequent cross matching of blood was thereby made difficult, and at a later blood transfusion incompatible blood was given

Treatment—The patient was being treated with potassium citrate for a urinary infection, and this was continued for some time before it was recognised that she was oliguric This caused a serum potassium level of 8 m eq per litre on the fifth day The patient was treated with the intragastric régime throughout the oliguria and with resins between the fifth and eighth days The serum potassium level was reduced to 4 5 m eq per litre after three days' treatment with resin, 103 m eq of potassium being removed by the resin and 26 m eq in the urine On the eighth day the patient had a satisfactory diuresis, and she made an uninterrupted recovery

Resin therapy would have been unnecessary in this case if potassium citrate had not been used to alkalinise the urine Sodium citrate or bicarbonate is a much safer therapeutic agent for this purpose in any condition where there is danger of the development of anuria or oliguria

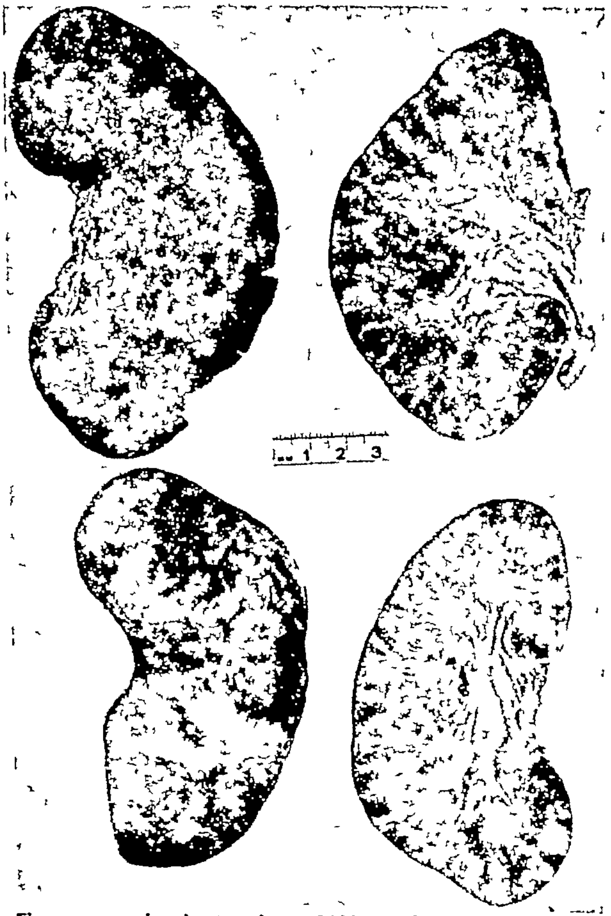

Fig - 1 and cut surfaces of kidneys of case 1, showing renal cortical necrosis

TABLE I—EFFECT OF RESIN THERAPY ON
LEVELS

Subject	Duration of resin therapy	Serum potassium level (m eq per litre)		Total of potassium removed by resin (m.eq)	P pr
		Before therapy	After therapy		
Case 1	5 days	6 0	4 3	270	[illegible]
Case 2	3 days	8 0	4 5	103	[illegible]
Case 3	6 days	8 2	4 9	280	[illegible]
Case 4	18 hours	9 2	—	7	[illegible]
Case 5	3 days	6 3	3 7	91	[illegible]
Normal person	4 days	4 4	3 3	84	[illegible]

Case 3—This patient was treated throughout at Middlesex Hospital She was a previously healthy gi 17, who had had a sudden and unexplained anuria.

Treatment—She was treated by intragastric drip eleventh day, when vomiting became so troublesome was discontinued and the intravenous régime was On the twelfth day the serum potassium level h 8 2 m eq per litre Treatment with resin reduced 4 9 m eq per litre within five days, 280 m eq of being removed Her blood urea level had been 12 100 ml on the third day of the anuria and had risen mg per 100 ml by the sixteenth day, when she sta pass small amounts of urine A satisfactory diures occur until the 21st day of the oliguria, when the blo level had risen to 510 mg per 100 ml, although the potassium level remained below 5 m eq per litre. made an uninterrupted recovery

Death from hyperkalæmia would almost have occurred had active steps not been taken to the serum potassium level

Case 4—This patient was seen and treated at hospital and was never fit for transfer He was a healthy young adult male who sustained a severe injury of both thighs His urinary output was sa for the first three days after the accident, but after th was severe oliguria On the fifth day the blood urea 294 mg per 100 ml and the serum potassium level 9 per litre

Treatment was given by the intragastric drip, but treatment was not started until the seventh day Th died eighteen hours after the first dose of resin, there been no improvement in his condition

At necropsy the resin was found to have been within the stomach and in this site to have taken 7 0 m eq of potassium A severe crushing injury of th muscles and the changes of acute tubular necrosis kidneys were found

Resin treatment should have been given several earlier, in the grave condition of the patient whe seen dialysis methods would have been preferable facilities were not available locally and the patient unfit for transfer This case illustrates how very the serum potassium level may rise in the crush owing to release from damaged muscle

Case 5—This patient was transferred to Hamm Hospital on the third day of anuria He was admitted acute suppurative parotitis and anuria of two days' He had previously had relapsing pneumonia and coccal infections associated with leucopenia, but o occasion there was adequate polymorph leucocytosis considered that the anuria was almost certainly on chronic uræmia since the blood urea level was ver being 440 mg per 100 ml, there was severe acidos plasma bicarbonate level being 9 0 m eq per litre, and was a normochromic anæmia with hæmoglobin 7 0 g pe

Treatment—Since there was no previous history of renal disease, the patient was treated as a case of anuria, the intravenous régime being used in view parotitis The latter was treated by incision and terra by mouth since that was the only antibiotic to wh causal staphylococcus was sensitive The plasma level was 6 3 m.eq per litre and three days' treatme resin was given, which reduced the level to 3 7 m.eq 91 m eq of potassium having been removed The b to 584 mg per 100 ml., and the patient died in coma inth day of the anuria

sy showed that there was severe secondary amyloid e liver spleen adrenal cortex, and a single horseshoe The renal disease was clearly severe and irreversible as recovered at necropsy from all the anatomical of the gastro-intestinal tract except the ileum The lk of the resin was however retained in the stomach g partial ileus

Results

in the patients with anuria and in the normal there was considerable exchange of sodium ion assium ammonium calcium and, occasionally, um ion The serum potassium levels fell in all the (table I) In cases 2 and 3 a satisfactory diuresis ace soon after the fall of the serum potassium d the patients made a good recovery In cases 1 although the serum potassium level dropped orily there was progressive retention of nitrogen h patients died in coma Necropsy showed that l damage, due to cortical necrosis and amyloidosis vely was severe and irreversible. Case 4 was too late since the serum potassium level was q per litre when therapy was started Death

ace within eighteen hours of resin being given necropsy almost all the resin was found in the h and very little potassium had been taken up late stage the patient should have been treated ysis but if resin had been administered earlier ly such a dangerous hyperkalæmia would have prevented In the normal person the serum um levels fell in two days from 4·4 to 3·3 m eq but did not drop any further although progressive um depletion continued

e II and figs. 2 and 3 present the results of analyses ns combined with resin obtained from the patients e normal person On a normal diet calcium and um are taken up in preference to univalent On the modified Borst diet containing 30 m eq um a day, considerable quantities of calcium were ged When resin is given by retention enema take of potassium increases with the period of on The comparatively long periods for which it is ry to retain the enemata before significant ge takes place diminishes the efficiency of this f administration in ill patients. Even when the was retained for eighteen hours the uptake of um was less than when resin is given by mouth he patients exchange for potassium was greater ably because they were on an electrolyte free d therefore there was less competition with divalent In most cases, however there was considerable of ammonium ion as well as potassium nia produced by bacterial breakdown of urea, is t in high concentration in the intestinal contents mic patients Fortunately potassium is taken up

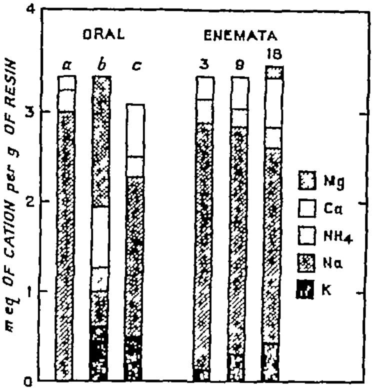

Fig. 2—Normal person. Cation combined with resin and expressed as m.eq per g : a as administered ; b recovered from fæces (normal diet) ; c recovered from fæces (Borst diet) ; 3 9 and 18 after retention of enemata for 3 9 and 18 hours respectively

preferentially to ammonium ion by exchange resins Ammonia formation proceeds in fæces after they have been discharged from the body Since stools are usually alkaline the ammonia escapes but becomes fixed to resin if this is present Thus an uptake of 0·80 m eq of ammonium ion per g of resin was found on incubation of the resin with excess of normal fæces for twenty four hours This was increased to 1·20 m eq per g if 1% urea had been previously added

In case 5 resin was recovered at necropsy from the contents of the stomach jejunum and the various anatomical divisions of the colon. No resin was obtained from the ileal contents. It was found that potassium uptake had increased progressively as the resin passed down the gut All the specimens contained considerable amounts of ammonium ion but there was no free acid in the stomach of this patient and presumably bacterial action extended to a higher level of the gastro intestinal tract than is usual

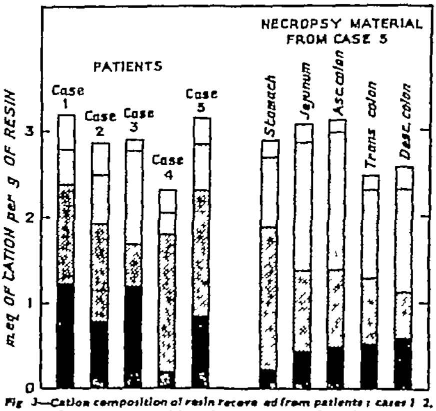

Fig 3—Cation composition of resin recovered from patients ; cases 1 2, 3, and 5 average composition of resin recovered from fæces in life ; case 4 resin recovered from stomach at necropsy Necropsy material from case 5 shows the composition of resin obtained from the various parts of the gastro-intestinal tract.

Discussion

An increase in the level of extracellular and plasma potassium to about 10 m eq per litre may cause death from cardiac arrest (Finch et al 1946) In anuria a rising plasma potassium level results from endogenous protein metabolism, with consequent transfer of potassium from the intracellular to the extracellular phase Gamble (1951) has shown that the average endogenous consumption of protein during a period of fasting is 70 g a day When 100 g of glucose is given each day this is reduced to 40 g, but no further decrease results from a greater carbohydrate intake It can therefore be assumed that anuric patients have an endogenous protein breakdown of at least 40 g a day In many cases this is considerably greater owing to fever, involution of the uterus in postpartum patients, and removal of damaged tissue, as in the crush syndrome This endogenous metabolism leads to a total increment of non protein nitrogen of at least 6 4 g a day If the average total volume of the body-water is 49 litres, this corresponds to an expected minimal daily increase of the blood-urea level of 28 mg per 100 ml Since 1 g of protein nitrogen is equivalent to 2 7 m eq of potassium (Reifenstein et al 1945), there is simultaneously a release of 17 m eq of potassium from the tissues into the extracellular compartment

The carbohydrate in Bull's régime amounts to 400 g daily Although an intake of more than 100 g of carbohydrate a day does not cause any greater protein sparing, it does reduce potassium levels in the extracellular fluid by increasing glycogen synthesis, which is accompanied by transfer of potassium into the body cells (Fenn 1940) Only the glycerol fraction of fat is effective in this respect, and there seems to be no theoretical reason for giving 100 ml of oil if it causes any nausea or other symptoms of gastro intestinal upset We therefore do not hesitate to reduce the oil intake to 25 ml a day if there are any such symptoms This amount of fat is included since it produces an opaque white emulsion which conceals from the patient that his strained vomit is being added to the intragastric drip as the most satisfactory method of restoring electrolyte loss

The resin by the oral route has been found to exchange 0 5–1 2 m eq of potassium per g, corresponding to a total of 20–75 m eq a day at the dosage of resin suggested This is usually considerably more than the daily accumulation in the extracellular compartment, and therefore, as in all the patients except case 4, there was a progressive reduction of plasma-potassium level. It has been shown (fig 3) that potassium uptake continues throughout the gastro intestinal tract, and that the exchange in the stomach is small It follows that there must be a short latent period before much effect is produced This may be further prolonged in gravely ill patients because there may be a partial ileus in some cases of anuria, with accumulation of resin in the stomach, as seen in cases 4 and 5 The administration of resin by rectum is far less effective, but is still of value if the enema can be retained long enough Where the plasma-potassium level is already greatly increased when the patient is first seen, it is preferable to give the resin by both routes Further uptake of potassium by resin administered by enema can hardly be expected after the first oral dose has reached the rectum An oral carmine marker is a useful indication of this Further exchange of potassium will occur as long as resin is passing through the gut, and may be expected to continue for about two days after the last oral dose We recommend that resin should be given as soon as the serum potassium level rises above 6 m eq per litre The effect should be controlled by daily estimations of serum potassium level, and the resin should be discontinued as soon as the value falls below 5 m eq per litre If it is stopped at this level, t [illegible] danger of serious hypokalæmia The observations on the normal person show that the serum level is rapidly reduced by the resin to about 35 per litre, and continued administration is still in removing potassium without causing any reduction in the serum-potassium level At this of depletion serum potassium levels are maintained low normal value from intracellular reserves and to be any guide to the magnitude of potassium

In some of the anuric patients the resin sodium in exchange for a considerable ammonium ion The highest ammonium values obtained from stools of case 3 and from the gut obtained at necropsy from case 5 In both of was probably some increase due to post mortem tion of ammonia, since in case 3 the stools had kept for a few days before analysis, and in case intestinal contents were not obtained until hours after death Considerable uptake of ion was found, however, in some stools analysed diately after defæcation A high ammonia stools from uræmic patients has been reported by and Dick (1933), it is derived from bacterial position of urea present in high concentration intestinal contents Resin treatment probably the amounts of ammonia eliminated, since reab this cation is prevented The amount of nitrogen by this means is small, and was always considerabl than 1 g a day Its main importance in resin is not therefore a significant increase of nitrogen e tion but rather an undesirable reduction of pot exchange by cation competition

The diets used in the treatment of anuria virtually no fæcal residue In the balance on the normal person the average daily weight of was exactly three times that of the resin ingested the same period The resin increases in weight and a half times when thoroughly moistened and is allowed to drain off It therefore follows th fæces consisted of little other than moistened res intestinal mucus There was never any tend fæcal impaction or any difficulty in evacuation stools, but it was *considered* safer to give a small wash if a bowel movement had not taken place previous two days It is essential to use small of fluid, since colonic absorption of water takes may easily lead to water intoxication

Scheme for Treating Anuria with Resins

Diet

The patient is treated as a routine with the gastric drip régime of Bull et al (1949) This of the daily ingestion of an emulsion of 100 ml of oil in 1 litre of 40% glucose If the patient small quantities of urine, the same volume of extra is added to the drip the next day If there gastro intestinal symptoms the amount of fat is diately reduced to 25 ml daily, since the extra provided by the excess fat neither diminish end protein metabolism nor favour synthesis of gl The patient's vomit is strained and added to the the most satisfactory method of preserving elec balance If vomiting or other gastro intestinal sym persist the intragastric drip is discontinued, intravenous drip of 1 litre of 40% glucose a day through a polythene catheter passed via an ante vein into the superior vena cava Only small water equivalent to the preceding day's urine are given by mouth

Control of Infection

Scrupulous attention is paid to oral hygiene muscular penicillin 1 mega unit is given daily

Biochemical Control

After a preliminary assessment of the levels of potassium, chloride, bicarbonate, glucose, and urea

treatment is controlled by daily determinations
ssium urea and glucose Resin treatment is
as soon as the serum potassium level rises above
per litre and is discontinued when it falls below
per litre The resin is given orally at a dosage of
ree or four times daily Daily retention enemata
ing 30 g of resin are given following a small
rash Enemata are discontinued as soon as oral
belled with an oral carmine marker given with the
se is evacuated If the plasma potassium level
ove 9 m.eq per litre despite resin therapy, arrange
are made to treat by dialysis either peritoneal
or the artificial kidney being suitable for combina
th resin treatment This will be extremely rare
of the large amount of potassium removed by
n but may conceivably occur in cases where there
n considerable tissue damage, as in severe burns
uria and in the crush syndrome
opriate amounts of soluble insulin are given by
n twice or three times daily if the blood-sugar
ses above 200 mg per 100 ml Many patients
a high blood-sugar level on these dietary régimes
appears logical to favour glycogen synthesis and
ient transfer of potassium into the cells by
ous insulin

a

nsfusion of packed cells is given if the hæmoglobin
han 70% on the Haldane scale

COMMENT

suggested régime differs from that of Bull (1952)
that every effort is made to avoid potassium
by the *early* use of resin, that less insistence is
a high fat régime for the reasons discussed above,
it insulin is used routinely if there is any tendency
erglycæmia.

Summary

treatment with a sodium sulphonic ion-exchange
five cases of anuria or severe oliguria complicated
perkalæmia is reported. The serum potassium
as satisfactorily reduced in four of the patients,
nal recovery in two

patients died from severe irreversible renal
and one from hyperkalæmia before the resin
xert any significant effect

resin is more effective in removing potassium when
by mouth than when it is given by retention

resin continues to take up potassium in exchange
lium throughout its passage through the gastro
al tract. The effect is therefore delayed after
t dose and prolonged after the last one.
heme of routine treatment with ion-exchange
is given for anuria and severe oliguria

hanks are due to Bayer Products Ltd. for the sodium
ic ion-exchange resin, and to the various physicians,
s, and obstetricians who made their patients available
trial.

SENIOR MEDICAL REGISTRAR, LONDON HOSPITAL

Epidemics of bronchitis in young children are probably exceedingly common yet they have been relatively seldom described Various hypotheses have been advanced to explain these outbreaks, but their cause remains obscure We describe here two epidemics of acute bronchitis bronchiolitis, and bronchopneumonia in young children and examine possible infective causes in particular the influenza viruses

Rilliet and Barthez (1884) pointed out that the most severe forms of acute bronchitis in young children might occur in epidemics. Outbreaks of bronchiolitis have been described more recently in England by Hubble and Osborn (1941) in America by Adams et al (1942) Greengard et al (1941) Pratt (1944) Henderson and Rosenzweig (1951) and Walker (1952) and in France by Marquézy and Debray (1950) All described multiple cases of severe bronchitis, bronchiolitis or bronchopneumonia occurring within a relatively short time in children mostly aged less than 2 years.

The most likely of the possible causes seems to be one of the influenza viruses. For more than a century it has been known that in adults bronchitis and pneumonia are related to epidemic influenza (Ministry of Health 1920) and the increase in mortality associated with influenza is usually greatest in young children and old people (Burnet and Clark 1942) On the other hand West (1884) pointed out that catarrhal epidemics were not uncommon among the young when there was no general prevalence of the same class of ailments in the adult population. Again, Wollstein and Goldbloom (1919) mention that, when the pandemic of influenza started, there was a general impression that children were not affected by it. They themselves maintained however, that, as soon as the influenza spread from the Services to the civilian population the incidence of pneumonia in children did increase Hubble and Osborn (1941) noted that all their 50 cases of bronchiolitis occurred in the first ten weeks of 1940 although they suggested influenza as the cause they admitted that proved viral influenza was not prevalent in England at the same time. Anderson et al (1953) found that in Glasgow the greatest absolute increase in pneumonia notifications in the 1950–51 influenza A epidemic occurred in those aged 4 years or less On the other hand, during the same epidemic Semple (1951) in Liverpool Burn (1951) in Salford, and Fry (1953) in his practice in Kent noted that infants and young children seemed to be relatively unaffected Stuart Harris et al (1949) moreover pointed out that in Sheffield in December 1947 and January, 1948 when there was no epidemic of influenza, there were more notifications of and deaths from, pneumonia in children aged less than 5 years than in the corresponding months of the succeeding year when there was an influenza epidemic They also showed that the number of cases of pneumonia in children aged less than 5 years was greater in February, 1949 than in March 1949, at the height of the influenza A epidemic It therefore seems that the relationship between influenza and pneumonia in children aged less than 5 years is not so constant or precise as it is in adults.

Several workers have suggested that these epidemics might be due to the virus causing primary atypical pneumonia " associated with increased cold agglutinins in adults (Nelson and Smith 1945, Adams 1948, Thompson and Spector 1949, Walker 1952) Others have emphasised the importance of infections of the upper respiratory tract—e g , colds and " febrile catarrh "—in conjunction with bacteria in the pathogenesis of acute bronchitis in children (West 1884, Cruickshank 1939, Holt and McIntosh 1940, Moncrieff et al 1953)

Material and Methods

This study was restricted to the London area during the two winters of 1949–50 and 1950–51

CLINICAL AND EPIDEMIOLOGICAL STUDY

As an indication of the incidence of bronchitis and pneumonia in children aged less than 5 years, the admission dates of all cases so diagnosed at four London hospitals have been grouped together by weeks numbered in accordance with the Registrar-General's Weekly Returns All cases of acute bronchitis, bronchiolitis, and pneumonia have been included throughout both winters from week 40 to week 13 inclusive Children with primary tuberculosis, bronchial asthma, bronchiectasis, fibrocystic disease of the pancreas, and congenital heart disease with heart failure have been excluded so far as possible, as have been cases occurring after measles or after whooping cough The hospitals from which these figures were obtained were the Hammersmith Hospital (hospital A), in West London, the Hospital for Sick Children, Great Ormond Street (hospital B), in Central London, Whipps Cross Hospital (hospital C), in East London, and St Andrew's Hospital, Bow (hospital D), in East London The age incidence and sex-incidence have been recorded for the admissions to three of these (hospitals A–C) A broad clinical analysis has been attempted for the cases admitted to two (hospitals A and B), whereas the radiological, bacteriological, and serological findings are presented only for cases admitted to hospital A

The mortality from respiratory infections has been derived from the number of registered deaths from influenza, pneumonia, and bronchitis in London, abstracted from the Registrar-General's Weekly Returns

The extent and timing of the influenza B epidemic in the first winter and the influenza A epidemic in the second have been assessed by three criteria

(1) The percentage of patients of all ages with respiratory infections whose sera, examined at the Virus Reference Laboratory, Colindale, showed complement-fixing ant to influenza B and influenza A to a titre (reciprocal dilution) of 32 or higher The onset dates of these pat illnesses have been grouped together by fortnightly per

2 yr –2 yr 11 mos	15	8	11	[illegible]
3 yr –4 yr 11 mos	13	15	16	[illegible]
Total 2–4 yr (incl)	28	23	27	[illegible]

(2) The number of new claims to sickness benefit weekly, in the London and Middlesex region, to the of National Insurance (Massey 1951)

(3) The weekly number of registered deaths from pneumonia, and bronchitis combined for the age-group

BACTERIOLOGY AND VIROLOGY

In the first winter, throat swabs, taken as admission as possible, were plated on to blood In the second winter material was aspirated from nasopharynx with a soft rubber catheter through a sterile trap bottle to a mechanical apparatus, and plated on to chocolate agar (for *philus influenzæ*) as well as blood-agar Mouse i tion was also used for the isolation of pneum which were tested against sera of types I, II, vii, and viii

In both winters specimens of serum from children were examined by one of us (J W F) Hammersmith Hospital for cold agglutinins Spe were also examined at the Virus Reference Lab Colindale, for *Streptococcus M G* agglutinins complement fixing antibodies to the viruses of psitta influenza A, influenza B, and *Rickettsia burneti* (Q In the second winter hæmagglutination inhibition were also done on specimens of serum in the acute convalescent stages against influenza A (PR 8) influenza A prime (A/Ankara/1/51) strains

Attempts to isolate a virus were on material obtained from 5 cases first winter

Results

BRONCHITIS EPIDEMICS

During the two winters 497 ch aged less than 5 years were admitted bronchitis or pneumonia to the hospitals, there being 263 adm during the first winter and 234 durin second

In the first winter 216 cases (82%) admitted during the last three wee 1949 and the first seven weeks of and 166 of these within a six week p It can be seen from fig 1 that week 1 week 4 of 1950 show the highest fi with 38 and 37 admissions respecti During the whole winter there were registered deaths in children aged l 5 years in London from " influe pneumonia, and bronchitis, of which occurred during the ten-week epi period, the greatest number of being recorded in week 1 and of 1950

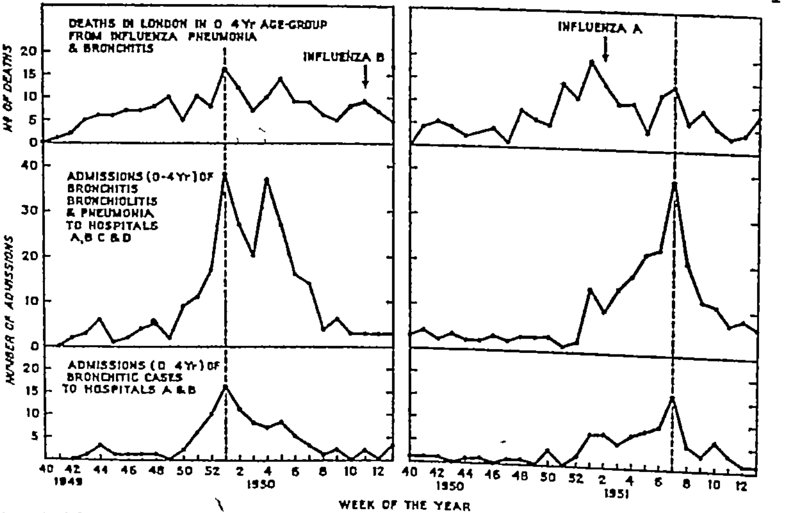

Fig 1—Timing of bronchitis epidemics Weekly number of admissions to four London hospitals of children aged less than 5 years with acute bronchitis, bronchiolitis, and pneumonia corresponds to an increase in the number of registered deaths in London pneumonia, and bronchitis. Peak of each influenza epidemic is indicated correspond to vertical interrupted lines in fig 2.

n the second winter there were 234 admissions, grouping of which also suggests an epidemic (fig 1) ough of the same duration it occurred three weeks r than in the previous winter There were 180 cases %) admitted in the first ten weeks of 1951 120 of n within a five-week period from week 4 to week 8 usive. There was only one peak of comparable in week 7 (with 38 admissions) although a lesser k (of 14 admissions) can be seen in the first week of New Year During the whole winter there were registered deaths in children aged less than 5 years ondon from 'influenza," pneumonia, and bronchitis, which 93 occurred in the ten week epidemic period t of the deaths took place in week 1 of 1951, and the t greatest number in week 7 (fig 1)

ical Analysis

f 364 children admitted to hospitals A, B, and C ly a third (117) were aged less than 6 months e than half (191) were aged less than 1 year and e than two thirds (252) less than 2 years Throughout winters there was a significant preponderance of e admissions which was chiefly restricted to children l less than 2 years (table I)

t hospitals A and B 217 cases were divided on the s of their physical signs into two groups; one with ralised signs of bronchitis (' bronchitic cases) the other with evidence of localised pulmonary lvement only (localised ' cases) It can be seen n table II that the bronchitic cases greatly out bered the localised especially during the height ch epidemic

he localised group (35 cases) was composed of a cellaneous collection of segmental or lobar pneu ins Except in the cases of staphylococcal pneumonia th empyema the children were not alarmingly ill ny time, and response to sulphonamides and/or biotics was rapid and clear cut. This group will be further considered here

he bronchitic group (182 cases) was made up of s of acute bronchitis, bronchiolitis, and broncho monia The chief clinical feature in most cases r dyspnœa of sudden onset usually following a few with a runny nose and cough Although there only 4 deaths (a mortality of 2 2%) many of these nts were alarmingly distressed, and 64 (30%) were ted in oxygen tents Nearly all the patients received either penicillin and sulphonamides, aureomycin or chloramphenicol. Recovery was usually rapid but not dramatic and the part treatment played in the outcome cannot be assessed in the absence of controls Some cases deteriorated after admission while on each type of treatment

The X ray appearances of 65 bronchitic cases at hospital A were reviewed In 27 the films were normal 20 showed generalised patchy shadows or streaking interpreted as patchy collapse and emphysema and 18 showed definite evidence of consolidation

White-cell Counts

In 50 bronchitic cases from hospital A total and differential white-cell counts were normal in 38 in only 12 was the absolute polymorph-count more than 7500 and in only 8 more than 10 000

Bacteriology

In the first winter during the epidemic period of 29 throat swabs taken on admission from bronchitic cases 24 yielded only *Strep viridans Neisseria catarrhalis* or micrococci, 4 *Staphylococcus aureus* and only 1 *Strep pneumoniæ* of undetermined type

During the epidemic period of the second winter material was aspirated from the nasopharynx in 24 bronchitic cases: 16 yielded *Strep viridans N catarrhalis* or micrococci 7 *Strep pneumoniæ* (2 of type VIII 1 of type VII and 4 of undetermined type) and only 1 *H influenzæ*

Virus Studies

During the epidemic in the first winter specimens of serum from 14 convalescent bronchitic patients from hospital A were examined for cold agglutinins and the complement-fixing antibodies to psittacosis, influenza A

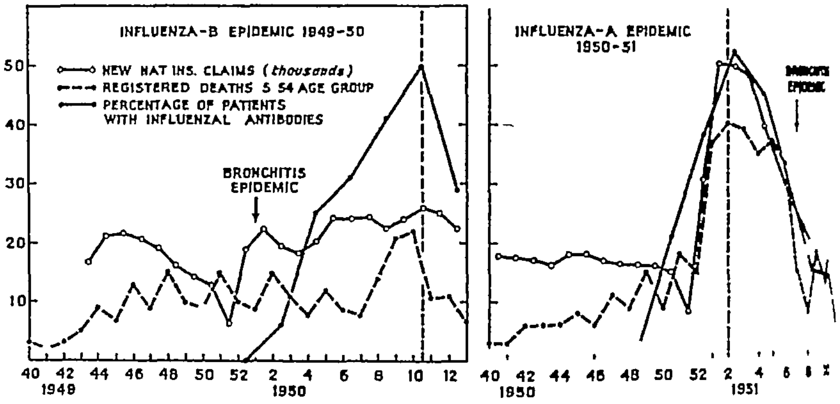

Fig 2—Timing of influenza epidemics judged by 3 criteria. Peak of each bronchitis epidemic by arrows which correspond to vertical interrupted lines in fig 1

influenza B, and Q fever All the tests gave negative results In addition necropsy material obtained from an infant, aged 8 weeks, who had died of bronchiolitis within twelve hours of the onset of his illness, was inoculated into fertile hens' eggs, ferrets, hamsters, and mice Throat washings from 3 other cases, obtained twenty-four hours, four days, and five days after onset respectively, were inoculated into fertile hens' eggs and hamsters No evidence of the presence of influenza or any other virus was obtained

During the epidemic in the second winter specimens of serum were similarly examined from 27 bronchitic cases, 25 were completely negative One boy (case 10 of table III), aged 14 months, showed an unchanging titre of 16 to influenza A on the 6th and 28th days of his illness A girl, aged 2 years, had a titre of 64 to influenza A on the 8th day of her illness and 32 on the 85th day These were the only cases in which complement-fixing antibody was detected, but titres such as these may persist for at least three months after infection with influenza Hæmagglutination inhibition (Salk) tests to influenza A (PR 8) and influenza-A prime (A/Ankara/1/51) viruses were done on paired sera from 13 of these children 10 showed a fixed or falling titre to influenza A (PR 8) (6 of these were infants aged less than 8 months and may have possessed passively acquired maternal antibodies, 4 were aged more than 1 year and therefore had probably acquired their antibodies as a result of previous infection), 3 showed a fixed titre to influenza A prime (A/Ankara/1/51), and 2 showed a low fixed titre to influenza B (Lee) In none of these cases did the findings, which are summarised in table III, suggest that any of the known influenza viruses had been responsible for any of the immediate illnesses

INFLUENZA EPIDEMICS

The influenza B epidemic in the first winter was mild in London It can be seen (fig 2) that, judged by the onset dates of the respiratory illnesses of patients examined for influenzal antibodies, it started soon after Jan 1, 1950, and reached its peak at week 10 or 11 The amount of clinical illness among the adult population associated with it was small, judged by the number of new claims to sickness benefit made each week to the Ministry of National Insurance, both the number of new claims and of registered deaths from "influenza," pneumonia, and bronchitis each week for the age-group 5–54 reached a maximum at about the same time

The influenza A epidemic in the second winter was by comparison severe There is good correlation between the percentage of cases showing influenza A antibodies, the number of new claims for sickness benefit, and the number of registered deaths from "influenza," pneumonia and bronchitis in the 5–54 age-group (fig 2)

Discussion

Epidemics of acute disease of the lower respiratory tract in children, aged less than 5 years, of sufficient severity to require admission to hospital occurred in London in each of the two winters of 1949–50 and 1950–51 Each lasted about ten weeks and was reflected in a simultaneous rise in the death-rate from respiratory disease in the same age group A clinical analysis of some of the cases admitted revealed that the epidemics were [illegible]iced by an explosive increase in the number of cases sharing in common the physical signs of a bronchitis About two thirds of this group had plicated acute bronchitis, and about a third bronchiolitis or bronchopneumonia We refer to together as the "bronchitic" cases and to the epi which they formed as the "bronchitis epidemics."

The occurrence of an epidemic of influenza B in 1950, and of influenza A in the winter of 19 provided an opportunity to study the relation these bronchitis epidemics to virus influenza. epidemiological observations suggest that virus was not in either winter the cause of the bro epidemics

(1) The bronchitis and influenza epidemics but did not coincide The peak of the bronchitis epi the first winter preceded the peak of the influenza B by ten weeks, that in the second winter followed the of the influenza A epidemic by five weeks

(2) The bronchitis epidemic during the winter of th influenza B epidemic (1949–50) was more severe than during the winter of the relatively severe influenza-A ep (1950–51)

Both these observations resemble those rep Stuart-Harris et al (1949) in Sheffield. The mor figures for the older age groups form a striking c being, as might be expected, much higher in the s winter, during the influenza A epidemic Al at the same time there was an increase in mo in children aged less than 5 years, this was smaller in the older age-groups, in contrast with the Anderson et al (1953) for Glasgow during the epidemic The weekly figures for London during winter (1950–51) show that there were two sep waves of deaths from disease of the respiratory in children aged less than 5 years, the first ass with influenza A and the second with the bro epidemic If both waves were grouped together single two month period, as done by Anderson (1953), the number of deaths attributed to infl in children aged less than 5 years would be undul These findings are against the view that influenza was the cause of the bronchitis epidemics

It is of interest that the first bronchitis epid coincided with that described by Marquézy and De (1950), who reported the puzzling finding of influe (hæmagglutination-inhibition) antibodies and cold tinins in many of the infants they studied C fixation tests on 14 of the children we exam however, showed no complement fixing antibod influenza virus A or B, no *Strep M G* or cold agglut and attempts to isolate a virus were also negativ 5 cases During the second bronchitis epidemic cases were examined by similar tests and 25 of were negative The 2 positive cases showed no ody titre and might have acquired their influenza ome time during the preceding influenza epidemic negative results in adults would exclude infection nfluenza virus However the reliability of the plement fixation and hæmagglutination inhibition in the diagnosis of influenza in children aged less 1 year is virtually unknown indeed there is an ation that their antibody response may be poor lter and Eliza Hall Institute 1951)

ie failure to isolate pathogenic bacteria from any a few cases in the present study and the normal rential white-cell counts in most of the cases suggest bacteria did not play an important part in the omics This conclusion is supported by the findings nderson (1953) and Landsman (1953), who could not late variations in the bacterial flora of the upper iratory tract, particularly pneumococci with the lence of infections of the lower respiratory tract in lren and suggested that an unknown factor possibly in nature" was the principal contributory agent ie production of pneumonia in infants

ie titres of cold agglutinins (up to 32) and of *Strep* agglutinins (up to 10) observed do not reach the s suggested as significant by Crofton et al (1951) used the same technique in adults These findings est that the bronchitis epidemics were not due to an atile form of primary atypical pneumonia with ased cold agglutinins moreover their explosive ure indicates a short incubation period whereas that primary atypical pneumonia is about two weeks dan 1949)

he bronchitis epidemics might possibly have been ed by one of the several viruses responsible for the mmon cold and febrile catarrh which commonly t adults throughout the winter Neither the mortality res for the younger adult age groups, however nor figures for new claims to the Ministry of National rance suggest the presence of a simultaneous emic among the general population

i conclusion epidemics of a bronchitic illness broke among young children in London during the winters 949–50 and 1950–51 both were epidemiologically inct from influenza No evidence was obtained they were caused by a specific bacterium influenza s A or B psittacosis virus *R burneti* or the virus primary atypical pneumonia Their ætiology ains unknown

Summary

tudy of 407 children aged less than 5 years, with nchitis bronchiolitis and pneumonia admitted to London hospitals in the winters of 1949–50 and 0–51 showed that there was an epidemic of bronchitic ss lasting about ten weeks in each winter

he occurrence of these epidemics coincided with an ease in the number of registered deaths from fluenza, pneumonia, and bronchitis in children aged than 5 years in the London area

he bronchitis epidemic in the first winter was the re severe it preceded a mild influenza B epidemic bronchitis epidemic in the second winter was milder followed a relatively severe influenza A epidemic

Only 2 of 41 children examined serologically possessed ibodies to influenza virus and neither showed a rise of e No case showed a significant titre of Q fever or psittacosis antibodies, or of *Strep M G* or cold lutinins nor did cultures from the nasopharynx gest a bacterial cause

he ætiology of these outbreaks remains obscure

o wish to thank Dr Hilda Boffa Dr D R Barry Dr M lard and Dr O G Jones, of the department of bacteri y of the Postgraduate Medical School of London for bacteriological investigations; Dr B P Marmion he Virus Reference Laboratory Colindale for the attempts isolate a virus and the serological studies Dr C E. Newman Dr D MacCarthy Dr T P Mann and Dr A. P Norman for permission to investigate their cases Dr E Hindon Dr B D R Wilson and the medical committee of the Hospital for Sick Children, Great Ormond Street for allowing access to their case notes and records and Dr W P D Logan Dr E Hinden, and Dr B P Marmion for help and advice in the preparation of this paper

SUDDEN OR UNEXPECTED NATURAL DEATH DUE TO RUPTURED INTRACRANIAL ANEURYSM

SURVEY OF 250 FORENSIC CASES

T A R Dinning
M B Adelaide F R C S
REGISTRAR

M A Falconer
M Ch. N Z F.R C.S., F R A C.S
DIRECTOR

GUY'S MAUDSLEY NEUROSURGICAL UNIT, LONDON

Sudden or rapid death due to ruptured intracranial aneurysm is not uncommon According to forensic pathologists (Simpson 1947 Helpern and Rabson 1950) it accounts for 4–5% of all sudden and unexpected natural deaths At first sight this seems to be a completely unprofitable therapeutic field, but a few of these patients exhibit features either before or at the time of the fatal rupture which if they could be recognised in time might lead to surgical intervention and to prevention of the fatal outcome

Our study is based on 250 consecutive deaths due to ruptured intracranial aneurysm which were examined post mortem by Dr Keith Simpson Most of these cases were examined at the request of the coroner because the patient either had been found dead or had died quickly and unexpectedly Two fifths of the patients had survived long enough to reach hospital but more than half of these had died shortly after admission In the remaining cases, about a sixth of the total death had been delayed for a day or more but no satisfactory diagnosis had been made Dr Simpson kindly made available to us in his records not only his necropsy findings but also the salient features of the

TABLE I—AGE AND SEX IN 250 CASES OF RUPTURED ANEURYSM CAUSING SUDDEN DEATH

Age (yr)	0–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	
Males	0	3	1	14	16	21	21	9	
Females	0	1	4	7	18	36	50	36	
Total	0	4 (*1 6%*)	8 (*3 2%*)	21 (*8 4%*)	34 (*13 6%*)	57 (*22 8%*)	71 (*28 4%*)	45 (*18 0%*)	10 (4

clinical history Consequently we have been able to analyse these records to determine whether there are any significant differences between forensic cases and those ordinarily seen in hospital practice, and what proportion of the deaths might have been forestalled by prompt diagnosis and surgical treatment

Clinical Features

Age distribution—Just over half the deaths were of people aged 50–70 (table I) This is in keeping with most recently published reports of large series of intracranial aneurysms from hospital practice (Richardson and Hyland 1941, Hamby 1948, Hyland 1950, Ask-Upmark and Ingvar 1950) Leaking aneurysms do not, as is sometimes stated, occur chiefly in young persons They can occur at any age, and in each decade the prognosis is serious, the over-all mortality rate observed in most general hospitals being more than 50% (Falconer 1951), but there is no doubt that the prognosis worsens with advancing age, pari passu with the progress of widespread degenerative vascular disease

Sex distribution—Of the 250 patients 159 were female and 91 male, a ratio of 5 to 3 A similar slight preponderance of females was noted by Ask-Upmark and Ingvar (1950) and Meadows (1951) and is apparent in statistics relating to deaths in this country (Registrar-General, personal communication) However, in Dr Simpson's patients aged more than 50, females outnumbered males by 2 5 to 1, with aneurysms of the posterior cerebral artery the ratio was 3 to 1, and with aneurysms of the basilar and vertebral arteries 4 to 1 The reason for this curious preponderance of females is not known, but the preponderance is found in both forensic and hospital cases

Antecedent Stress or Trauma—In most of the forensic cases there was sufficient information to show whether an episode of undue physical exertion had either coincided with or shortly preceded the rupture, such an occurrence was noted in only 10 cases (4%) This again is in keeping with the observation of Magee (1943), that, in Service personnel who develop subarachnoid hæmorrhage, trauma or stress occurred as an apparent precipitating factor in only 8% It is perhaps noteworthy that no head injury was found in any of the forensic cases

Premonitory Symptoms—In this forensic series many patients had complained for some weeks or even months of slight or moderate headaches or of attacks of dizziness, but, in view of the frequency with which such non-specific symptoms occur in the general populace, in few patients could such symptoms, even in retrospect, have been identified at the time as premonitory Indeed in 164 cases (66%) the fatal attack seemed to come like a bolt from the blue It is noteworthy, however, that in 23 cases (9%) there was a previous history of subarachnoid hæmorrhage occurring from sixteen days to ten years earlier Such an incidence of previous attacks of hæmorrhage is also often apparent in hospital case-material

Necropsy Findings

Distribution of Aneurysms—274 aneurysms were found in the 250 cases, multiple aneurysms being noted in 6% of cases, a figure which is not out of the ordinary The various aneurysms were equally distributed between the right and left sides Their distribution seems comparable with that in unoperated hospital cases studied post mortem and with that in cases surgically (table II), except that at first sight it that in Dr Simpson's material there was a aneurysms situated on the supraclinoid portion internal carotid artery and an excess of the middle cerebral artery A possible explanation that it is often very difficult at necropsy, when the cisterns are solid with clot and the arterial is distorted, to decide just where the internal artery ends and the middle cerebral artery Arterial injection, by giving pictures of the arrangement comparable to those afforded in the by carotid arteriography, might prove very here Perhaps, therefore, some of the labelled as being on the middle cerebral artery actually situated on the internal carotid artery so, there may be no significant differences between distribution of aneurysms in forensic cases and in hospital cases This point will require further study

Other Findings—The size of an aneurysm to have no direct bearing on the severity of the rhage to be expected from it This forensic included aneurysms of all sizes from 1–2 mm in up to large aneurysms 4 cm in diameter, but in con with hospital experience most of the aneurysms small Intracerebral bleeding as well as subarac bleeding was often found with aneurysms of the an cerebral and anterior communicating arteries and of middle cerebral artery, a finding which agrees with in hospital material (Richardson and Hyland Robertson 1949) Dr Simpson also noted that only 80 cases (32%) was there a degree of atheroma cerebral vessels which was worthy of comment Fr in the patients aged more than 40 the incide cardiovascular disease, judged by definite hyper cardiac changes and/or noteworthy atheroma was 64% The importance of these conditions in predisp to rupture is therefore difficult to assess, for they are primary factors, and a similar incidence of cardi disease might well be expected in illness other aneurysm in comparable age groups (Meadows 1951)

TABLE II—COMPARISON OF DISTRIBUTION AND LOCA RUPTURED ANEURYSMS IN ORDINARY HOSPITAL AND FORENSIC CASES

Arteries	Fatal unoperated hospital series—37 aneurysms (Richardson and Hyland 1941)		Operated hospital series—70 aneurysms (Falconer 1952)		[illegible]
Internal carotid	26%	56%	47%	64%	2%
Middle cerebral	30%		17%		46%
Anterior cerebral	33%		32%		33%
Vertebral basilar, and posterior cerebral	11%		4%		[illegible]

Discussion and Conclusions

There thus appears to be no striking difference be this series of forensic cases and the ordinary ru hospital cases as regards age and sex, location aneurysms, and such predisposing factors as size of aneurysm, and pre existing cardiovascular e only striking difference so far apparent concerns the ration of symptoms for whereas in the hospital aterial the clinical course is usually sufficiently pro nged not only to enable the patient to reach hospital t also to permit of a correct diagnosis, in the forensic ses death was generally sudden rapid or unexpected ven when the forensic cases did reach hospital death ually took place so soon afterwards that it seems first sight that little could have been done to forestall

Indeed there may be little time even for diagnosis us in the whole series an approximate antemortem agnosis was forthcoming in only 57 cases (20%) d the correct diagnosis of subarachnoid hæmorrhage as made in only 17 cases (7%)

The question arises whether any of these deaths could ve been prevented either by prophylactic investigation d treatment before the fatal rupture or by prompter agnosis after rupture had occurred Until recently ch a consideration would have been academic and practical for the routine treatment of bleeding eurysms has been merely a matter of rest and quiet d in these circumstances earlier diagnosis in the forensic ses would have made little difference to the outcome t surgery is now making strides in this field and ports are appearing from several surgical centres owing that after the aneurysm has been first located d demonstrated by cerebral arteriography prompt rgical intervention can reduce the expected mortality more than 50% to a third or even less (Falconer 51, 1952 Mount 1951 Norlén 1952) Further experi ce may even improve these results and we have ely had a consecutive series of 20 recently bleeding eurysms operated on by either arterial ligation or aniotomy without a death The prospects for surgery non bleeding aneurysms should be even better because fferson (1952) and Johnson (1952) treated 113 such ses by carotid ligation without fatality

In this connection two important points emerge rstly in 23 (9%) of Dr Simpson s cases there was previous history of subarachnoid hæmorrhage from teen days to ten years earlier Subsequently when e fatal recurrence came, 18 of these patients died thin twenty four hours and only 5 survived for longer riods up to a week There would be thus little or opportunity to treat such patients if one had to wait til the second and probably fatal rupture Recurrence bleeding is an ever present risk with intracranial eurysms and although most recurrences occur while e patient is still in hospital under treatment for his st attack (Magee 1943, Falconer 1951) even after scharge from hospital there is a 20% chance of fatal current bleeding if patients are followed up for six ars or more (Hyland 1950) Considering that per taneous cerebral arteriography is fairly safe we feel at all patients who have had even a single and mild tack of subarachnoid hæmorrhage should be investi ted in this way and that, if an aneurysm is found me operation to lessen or prevent rupture should en be carried out To postpone cerebral arterio aphy until recurrent bleeding has appeared leads to e surgeon s being called on to treat the underlying dion under unfavourable conditions, and all too often the patient s death before appropriate treatment can en be started

The second point is that in 38 cases (15%) death s delayed for more than twenty four hours after the pture and in 15 of these for more than a week All t 3 of these patients had been in hospital sufficiently ng to be operated on if the correct diagnosis had en made and the necessary ready access to a neuro rgical centre had been available None however was treated.

Thus 56 cases in this forensic series (22%) exhibited ne feature which had its significance been recognised should have paved the way for precise diagnosis and treatment Not all of these patients of course would have survived, even in the best surgeon's hands but possibly a proportion could have been salvaged at least more than a half. The evidence therefore indicates that even in such a highly unfavourable selection of bleeding aneurysms as the forensic series just considered some of the deaths could have been prevented

We wish to thank Dr Keith Simpson for his kindness and encouragement

ALKALOSIS IN INFANTS

TREATMENT BY INTRAVENOUS INFUSION OF AMMONIUM CHLORIDE

REGISTRAR CHILDREN S HOSPITAL, SHEFFIELD

Severe alkalosis can be rapidly relieved by infusing ammonium chloride intravenously but the fear of toxic reactions and the need for biochemical control have prevented this from becoming a common therapeutic measure

Adults with alkalosis have been treated successfully with intravenous ammonium chloride (McCann 1922 Youmans and Greene 1925 Zintel et al 1943 Grace and Barr 1948) Forbes and Erganian (1946) gave nine infants with pyloric stenosis and alkalosis a solution of M/6 ammonium chloride in either isotonic saline solution or Ringer's solution by subcutaneous or intravenous routes for the relief of their alkalosis. These workers could not collect enough urine to report significant findings

Since more data are required on the effectiveness and safety of intravenous ammonium chloride in infants before this treatment can be advocated for them we report here the changes in clinical condition blood chemistry and urine findings resulting from the infusion of ammonium chloride in seven infants.

Material

Five (cases 1-5) of the seven babies had pyloric stenosis and alkalosis and were aged 2-11 weeks The two other infants (cases 6 and 7) who both had hydrocephalus and were aged 4 months, were in a good state of nutrition and hydration and showed no abnormality in acid base balance

Methods

Procedure

The babies with pyloric stenosis were seen soon after admission while dehydrated and alkalotic Specimens of

EFFECT OF INTRAVENOUS AMMONIUM CHLORIDE ON PLASMA-CARBON DIOXIDE AND PLASMA CHLORIDE LE SEVEN INFANTS

										Average = 0 43	

blood for analysis were taken from either the femoral vein or the sagittal sinus, and fluids were given via the scalp veins The first infusion was either 5% (*w/v*) glucose, or $^1/_5$ isotonic saline solution (0 18 g per 100 ml) in 4 3% (*w/v*) glucose, or $^1/_2$ isotonic saline solution in 4 3% (*w/v*) glucose The second infusion was aqueous *M*/6 ammonium chloride (8 9 g ammonium chloride per litre of water) The fluids were given slowly at rates varying from 0 5 to 1 5 ml. a minute The dose of ammonium chloride depended on the initial plasma carbon dioxide level and the reduction desired, on the assumption that 1 ml of *M*/6 ammonium chloride per kg of body-weight would reduce the plasma carbon-dioxide level by 1 vol per 100 ml During the infusions nothing was given to the infants by mouth Urine was collected through a many-holed catheter into a receptacle containing toluene and liquid paraffin

Analytical Methods

Heparinised plasma from blood collected under liquid paraffin was used for the determination of the carbon-dioxide level in either the manometric or volumetric apparatus of Van Slyke (1917) and Van Slyke and Neill (1924) The plasma chloride level was determined by Sendroy's (1937) method on 0 2 ml of plasma Sodium was precipitated as sodium zinc uranyl acetate and estimated by the modification of Butterworth (1951) The pH of the urine was determined as quickly as possible with a glass electrode and a Marconi pH meter Titratable acidity was estimated by titrating the urine against *N*/10 sodium hydroxide to pH 7 4 with phenol-red as indicator and a Lovibond comparator The method advocated by King (1951) was used for estimating ammonia These latter two methods were only sensitive enough to show large differences in the excretion of ammonia and titrable acidity

Results

Clinical

The clinical condition of the five babies with pyloric stenosis and alkalosis improved during the preoperative period They were quiet, and hunger and vomiting was not a problem The two infants with hydrocephalus remained well throughout their infusions

Blood Chemistry

The response to the infusion of aqueous *M*/6 ammonium chloride is shown in the accompanying table Four babies with pyloric stenosis (cases 1–4), who received 30–61 ml of ammonium chloride per kg of bod showed a fall in plasma carbon dioxide level of 14–1 per litre This was balanced by a rise in the p chloride level of 11–16 m eq per litre in the three (cases 1, 2, and 4) in whom it was estimated babies had received either glucose or $^1/_5$ isotonic solution in glucose immediately before the amm chloride The fifth infant (case 5) was given $^1/_2$ saline solution in glucose followed by 19 ml of chloride per kg of body-weight Technical diffic prevented the infusion of more ammonium chl and the amounts given did not reduce the plasma- dioxide level, although the plasma chloride level slightly (4 m eq per litre)

The two babies with hydrocephalus were g ammonium chloride at the rate of 10–15 ml per k body weight A response was observed in case 6, w plasma-carbon-dioxide level had fallen by 13 5 m eq litre twenty-three minutes after the end of the inf This fall was offset by a rise in the plasma-chloride of 8 m eq per litre

There was a significant change in the serum-so level in one of the three infants in whom this determi- tion was done the serum sodium level of case 4 was m eq per litre immediately before the infusion ammonium chloride, but six hours later, an hour a the infusion had ceased, it had fallen to 122 m eq litre Nine hours later the serum-sodium level was m eq per litre Parallel changes in the sum of chloride and carbon-dioxide levels were observed

Renal Response

The infusion of ammonium chloride was al preceded by either $^1/_5$ isotonic saline solution in gluc 5% (*w/v*) glucose It was therefore difficult to att any changes in minute volume and pH of the urine changes in the excretion of ammonia and titra acidity, to ammonium chloride alone There was, h ever, a pronounced difference in the diuretic respon the three dehydrated infants with pyloric ste (cases 1, 3, and 4) and the two normally hydrated inf (cases 6 and 7) The volume of urine excreted by dehydrated infants was not appreciably changed infusing ammonium chloride, and the urine mi volume was much lower than the rate of infusion, wh the two babies with hydrocephalus excreted such la volumes of urine that the minute volume approached exceeded the rate at which the infusion was given

-The pH of the urine remained 6 8–7 0 in two of the ro infants with pyloric stenosis (cases 1 and 3) and in se 4 *with pyloric stenosis there were falls in urine pH* m 7·0 to 5 8 and to 6 4 The pH of the urine in the o normally hydrated infants was 5·8–6 7 showing a idency to fall after the ammonium-chloride infusion t a high urine minute volume at that time masked y significant effect

The excretion of ammonia and titratable acidity during d after the infusion of ammonium chloride was studied four cases The amount of ammonia and titratable idity excreted in unit time was low and almost constant cases 1 and 3 with pyloric stenosis, in whom the pH is uniform. The two well hydrated infants (cases 6 d 7) excreted more ammonia in unit time when the ine minute volume rose The excretion of titratable idity in unit time was very low during the periods of idy

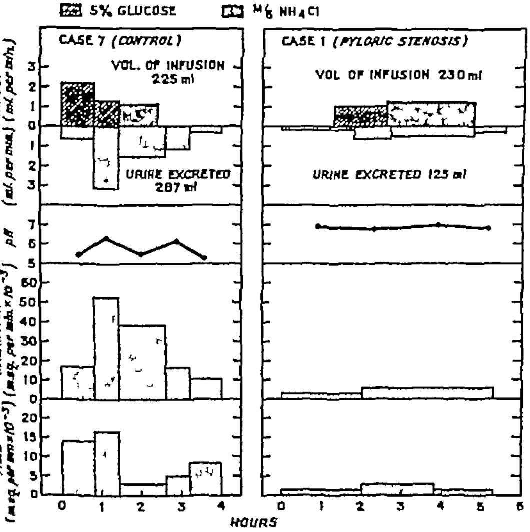
The results obtained in cases 1 and 7 are contrasted the accompanying figure

Toxicity

Cases 3 and 4 with pyloric stenosis developed genera ed convulsions In case 3 the convulsions occurred ien the baby had received intravenously 450 ml. of id containing 0 63 g of sodium chloride and had ssed only 30 ml of urine In case 4 the convulsions curred two and three quarter hours after the end of e ammonium-chloride infusion, when the infant had ceived 420 ml *of fluid containing* 0 3 g of sodium loride The serum-sodium level in case 4 fell from 0 m eq per litre just before the ammonium-chloride fusion to 122 m eq per litre six hours later

Discussion

The clinical condition of the infants with pyloric enosis improved before operation and hunger and stlessness were not appreciable Clearly it is impossible say whether these improvements were due to the ammonium chloride alone or to the intravenous fluids in general



rinary response of a dehydrated infant with pyloric stenosis (case 1) and of an infant in a good state of health and nutrition (case 7)

The fall in plasma-carbon-dioxide level to be expected from the infusion presents some problems (Bodansky 1949) Assuming that two thirds of the body weight was body water, and that the ammonium chloride given either intravenously or subcutaneously would permeate through the body water Forbes and Erganian (1946) calculated that the administration of 1 ml of *M/6* ammonium chloride per kg of body weight would reduce the plasma-carbon-dioxide level by 0 56 vol per 100 ml or *0 25 m eq per litre The decrease* which they observed was greater than this, and they *suggested that the* calculations ought perhaps to be based upon extracellular fluid and not on total body water Figures for the percentage of body weight occupied by the extracellular fluid of an infant obtained by the most reliable method (inulin) are not available Gamble s (1951) assumption that the extracellular fluid of an infant constitutes 25% of the body weight is compatible with the higher values *for sodium and thiocyanate space obtained* by Fellers et al (1949) in young infants, and for Na^{24} space in newborn infants (Flexner et al 1947, Perley et al 1951)

On the assumption that 25% of the body weight is a reasonable figure for the extracellular fluid of an infant aged 2–16 weeks the fall in plasma-carbon-dioxide level expected when 1 ml. of *M/6* ammonium chloride is infused is 0 67 m eq per litre This is considerably higher than the average falls observed However evidence has been *accumulating that about a third of the total body* chloride is intracellular (Deane et al 1952 Steele 1950) and it seems possible that the chloride infused would be distributed in the proportion of two thirds to the extracellular compartment and a third to the intracellular compartment In this event two thirds of the infused chloride would be available for reducing the plasma bicarbonate *level In these circumstances a fall of* 0 45 m eq per litre or 1 vol per 100 ml in the plasma carbon-dioxide level would be *expected from the adminis*tration of 1 ml of *M/6* ammonium chloride per kg of body weight. This figure is close to our *own* results and to the average result of Forbes and *Erganian (1946) which was 0 39 (range* 0 15–0·8) The average fall in our seven cases was 0 43 (range 0 00–0 9) whereas for the four cases of pyloric stenosis in which the calculated amount of ammonium chloride was given the fall in plasma carbon-dioxide level was *0 36 m eq per litre of plasma per ml* of *M/6* ammonium chloride per kg of *body weight (range 0 25–0·48) Thus* the fall in the plasma-carbon dioxide level after the infusion of ammonium chloride suggests that only two thirds of the infused chloride is available for *the reduction of the plasma bicarbonate* level in the extracellular fluid

The urine changes found by us could not be attributed to ammonium chloride alone, because of preceding infusion of saline solution or of glucose saline solution and these changes are not *therefore directly comparable with the* changes observed after the oral admini*stration of ammonium chloride in adults* (Sartorius et al 1949) and infants (Gordon et al. 1948) However there was a pronounced difference in the diuretic response between the normal *infants and those with pyloric stenosis* The latter were presumably deh ed and also in a state of sodi tion, and the lack of sodium for excretion may have been responsible for this difference The fall in pH which is expected after ammonium chloride infusion was masked by diuresis in the two children with hydrocephalus (cases 6 and 7) The increase in the amount of ammonia excreted during the periods of diuresis in these two children supports Wolf's (1947) contention that the excretion of ammonia is primarily a function of urine pH and does not suggest that any appreciable amount of the infused ammonium chloride was passing into the urine

The convulsion which occurred in two of our babies with pyloric stenosis treated with infusions of ammonium chloride were different from the toxic reactions reported previously Zintel et al (1943) described one febrile reaction and two complaints of scotoma during infusions of ammonium chloride to twelve adults Karr and Hendricks (1949) reported very severe reactions in dogs when ammonium salts were infused at a rate greater than 1 m eq per kg of body-weight a minute During preliminary experiments on dogs and rabbits Forbes and Erganian (1946) induced excessive salivation, hyperpnœa, and drowsiness when 20–30 ml of *M*/6 ammonium chloride per kg of body weight was infused intravenously in forty five minutes, and stupor and convulsions resulted when the speed of the injection was increased. They observed one toxic reaction in their nine infants with pyloric stenosis when 30 ml of *M*/6 ammonium chloride per kg of body-weight was infused in eighteen minutes This infant developed transient pallor, irregular respiration, brachycardia, and occasional twitching of the eyelids and hand Forbes and Erganian (1946) and Karr and Hendricks (1949) concluded that the toxicity of the infused ammonium chloride was directly related to the speed of the infusion It is unlikely that the convulsions observed in the present investigation were caused by the toxicity of ammonium ions, because the rate of infusion was less than 0 04 m eq per kg of body-weight a minute, and because of the nature of the reactions and the delayed onset after the infusion ceased Evidence that these convulsions were due to " water intoxication " is examined in a separate article to be published by two of us (S A D and K S H)

Mild cases of alkalosis can be satisfactorily treated with intravenous saline solution, but severe cases may need a more rapid relief of the alkalosis because of the risks of tetany and irreversible renal damage Some workers have treated severe alkalosis with ammonium chloride in either isotonic saline solution or in Ringer's solution Such a procedure makes it difficult to treat the patient as an individual and to calculate the fall in plasma-carbon dioxide level which a given dose of ammonium chloride should produce , yet it is undoubtedly necessary to replace the sodium and other electrolytes which have been lost by vomiting (Gamble and Ross 1925, Gamble and McIver 1925) Our findings suggest that the sodium lost should be replaced and dehydration relieved, preferably with $^1/_2$ isotonic saline solution, before attempts are made to correct the alkalosis The present investigation shows that the intravenous infusion of ammonium chloride for the relief of alkalosis in infants is safe if given slowly to a child who is not in a state of sodium depletion

Summary

Aqueous *M*/6 ammonium chloride was given intravenously to seven infants five with pyloric stenosis and alkalosis, and two with hydrocephalus who showed no abnormality in acid base balance

On the assumption that two thirds of the infused chloride is available to lower the plasma carbon dioxide level of the extracellular fluid, the fall expected from the infusion of 1 ml of *M*/6 chloride per kg of body-weight is 0 45 m eq per litre The fall observed by us was 0 43 ([illegible] m eq per litre) The infusion of glucose and glucose saline solution before the infu ammonium chloride prevented the study of the response to ammonium chloride alone, but the in the two controls was significantly greater tha infants with pyloric stenosis and alkalosis

Generalised convulsions developed in two cas pyloric stenosis, but these were not caused by ammonium chloride They were thought to be of " water intoxication "

The intravenous infusion of ammonium chloride effective and rapid method of correcting alkalos is safe when adequate precautions are taken

We wish to thank Prof R S Illingworth for his adv the preparation of this paper , Miss E Finch, M SC, for cooperation , Dr J L Emery for laboratory faci advice , and the nurses of the Children's Hospital, for their help The solutions of ammonium chlorid intravenous use were supplied by Allen & Hanburys Ltd

HEXAMETHONIUM IN POLYVINYLPYRROLIDONE

EDMOND A MURPHY
M D Belf
MEDICAL REGISTRAR

JOHN EASTWOOD
M B Lond.
HOUSE PHYSICIAN

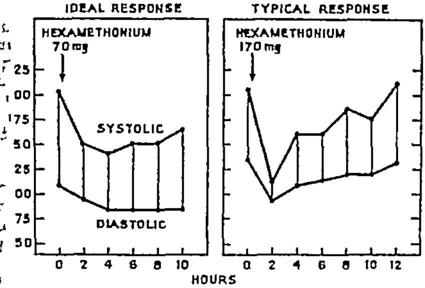
HALIFAX GENERAL HOSPITAL, YORKS

MORE than three years' study of the therapeutic of the methonium compounds in hypertension provided abundant evidence of their value (C and Robertson 1950, Smirk and Alstad 1951, Mackey Shaw 1951, Murphy 1951) Since the aim of to produce a sustained lowering of the blood pressure duration of effective action by the different routes great importance This is summarised in the accompanying table The duration of effect by the subcuta route has been shown to increase with the size of the d Most workers prefer this route, for action is pre and the patient can give himself the injections

DURATION OF EFFECT

Route	Action starts in	Maximal effect in (min.)	Duratio actio (hr.)
Oral	Up to 7 hours	—	6
Subcutaneous	15–30 minutes	25–30	3
Intramuscular	—	30	5
Intravenous	About 2 minutes	5	1-2

(See Mackey and Shaw 1951 Smirk and Alstad 1951 1951 Masini and Rossi 1951 Finnerty and Freis 1950, Kil and Smirk 1952)



1—Ideal and typical responses of blood-pressure to hexamethonium

o maintain the blood pressure within the desired its throughout the active part of the day it is necessary give three injections (Freis 1951) To obviate the need this various methods have been used

1) Combined oral and parenteral therapy with or without r drugs (Freis 1951)

2) The addition of vasoconstrictors to the injection irk and Alstad 1951)

3) Solution in a medium which delays absorption (almond dextran or polyvinylpyrrolidone [Smirk and Alstad 1951 ini and Rossi 1951])

4) Continuous injection throughout the twenty four hours an electrically operated syringe (Smirk 1951)

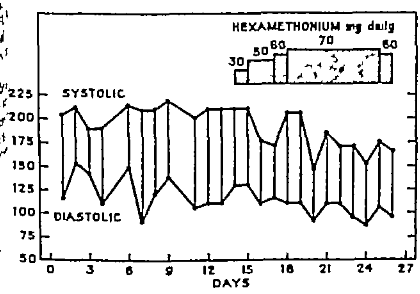
Most of these methods are ineffectual or impracticable solutions in polyvinylpyrrolidone are worthy of ther trial The solvent is a plasma substitute and was first used to delay the absorption of the solute Masini and Rossi (1951) later Smirk (1952a and b) orted on it favourably There is no evidence that solvent is harmful in the dose used or that it agonises the effect of hexamethonium

Investigation

We have therefore investigated the duration of effect blood pressure of one subcutaneous injection a day a solution of 20% hexamethonium bromide (*w/v*) in lyvinylpyrrolidone with 0 5% chlorbutol added as a servative and tried to find whether the size of the se modifies the effect No attempt has been made to dy the cases over a long period.

Five cases with severe hypertension, severe symptoms, d a grade III or grade IV retinopathy (Wagener and ith 1930) were studied All were submitted to a ndard routine of investigation designed to eliminate primary causes of hypertension cases with any evidence of coronary or cerebral arterial disease were excluded All had electrocardiographic changes indicating hypertension and enlarged left ventricle on radiography All were proved to be sensitive to an aqueous solution of intravenous hexamethonium One had been treated with dehydrogenated alkaloids of ergot (Rothlin 1952) with little success The patients were kept in hospital for fourteen days before treatment was started they were ambulant but not allowed unusual exercise Their blood pressures during this period were recorded daily with the patient standing at the same time and so far as possible, by the same person All satisfied the definition of hypertension given by Evans (1949)—i e a blood pressure of 190 mm Hg systolic and/or at least 110 mm Hg diastolic on three successive occasions in the presence of clinical radiological, and electrocardiographic evidence of arterial change

The initial dose determined by a modification of the Freis test (Murphy 1951) was given subcutaneously Great care was taken that the dose was accurately measured and that the needle was not accidentally inserted into a vein Blood pressure readings were then taken, under the conditions specified above at two hour intervals until the tenth or twelth hour



2—Cumulative effect of hexamethonium on blood-pressure ecorded on each occasion before the daily dose of this substance.

Results

An ideal response and a typical response of the blood pressure are shown in fig 1

In most cases the minimal systolic and diastolic blood pressures were reached within the first four hours but in one case it was reached at the eighth hour Appreciable hypotensive effect was at times apparent for as long as twelve hours. Considerable variation was noted from day to day with constant dosage despite careful measurement of the preparation by the doctor or by a senior nurse because the solution is viscous and more difficult to handle than the aqueous solution.

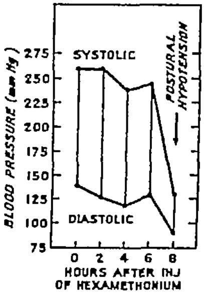


Fig 3—Late onset of postural hypotension after hexamethonium

The duration of action of the preparation does not seem to depend on the dose but to prove this it would be necessary to space the doses at intervals of days to obviate the effect of the development of tolerance

Evidence of cumulative effect was noticed in one case (fig 2) Although there was some variation there was a downward trend in the blood pressures even where the dose was kept constant

The side-effects noted were dizziness postural hypotension, constipation, loss of appetite and intestinal distension and colic There appears to be no lessening of the intestinal and other side-effects of hexamethonium, though the incidence of postural hypotension is lower Usually faintness and postural hypotension were noted in the first two hours In several cases however they came on late (fig 3) Though this may be due to the masking of hypotension in the earlier readings by physical activity the possibility that it is due to irregular absorption from the depot must also be borne in mind This unpredictability of the development of hypotension is more inconvenient than that from simple aqueous solutions of hexamethonium and in one case was gravely incapacitating

Summary

Hexamethonium in polyvinylpyrrolidone seems to have an effective hypotensive action which persists for six

to twelve hours and in some cases throughout the twenty-four hours, with a slight tendency to be cumulative Provided that its effect is constant throughout twelve hours (and this cannot always be achieved), one injection of the preparation given in the morning will suffice, because blood-pressure naturally falls at night Irregularities of action, with the production of postural hypotension, however, lessen its value

Our thanks are due to Dr L Glick and Dr J H Follows for permission to publish results on some of their cases, and to the former for his advice, and to the sisters and nurses of the Halifax General Hospital for their patient industry in taking hundreds of blood pressure readings Messrs May & Baker supplied the hexamethonium bromide in polyvinyl pyrrolidone and much otherwise inaccessible information

A NEW METHOD FOR THE DIFFERENTIATION OF SICKLE-CELL ANÆMIA FROM THE SICKLE-CELL TRAIT

J M VANDEPITTE
M.D Louvain

L A LOUIS
M.D Louvain

From the Institut de Médecine Tropicale Princesse Astrid, Léopoldville, Belgian Congo

Two recent discoveries of fundamental importance have given new interest to the study of the sickle cell anomaly

The first is the recognition of the fact that sickle cell anæmia (S C A) is far from rare on the African continent Before 1950 only sporadic cases of this condition had been reported there, although it was well known that 25% of natives of Central Africa harbour the asymptomatic sickle cell trait (S C T) Until very recently Raper's (1950) estimate that only one African in more than a thousand carriers of the trait develops S C A had never been contested seriously, but in 1951 Lambotte Legrand and Lambotte-Legrand, working at the Red Cross children's hospital at Leopoldville, reviewed 100 cases of S C A in African children, and Foy et al (1951), in Kenya, confirmed the high incidence of S C A in babies under twelve months of age

The second discovery is the demonstration that S C T and S C A are two related, yet sharply distinct, entities The two conditions do not merge but can be differentiated by genetical analysis (Neel 1949) as well as by the amount of the responsible abnormal hæmoglobin component (Pauling et al 1949) This discovery has considerable clinical interest because in previous years the point of view that every sickle-cell carrier was a possible candidate for S C A found rather widespread acceptance (Beet 1947) This older concept must now be abandoned If we can exclude with certainty the existence of S C A in a person whose erythrocytes are capable of sickling, we can feel assured that this red cell anomaly will not influence his later life On the contrary, once S C A has developed, it will never revert to the inoffensive S C T It follows from this entirely new concept that there is an urgent need for simple and reliable diagnostic criteria to differentiate between the two conditions This is esp true in tropical Africa, where S C T is often grafted on to anæmias of other origin and eve may be masked by some other blood disturba the absence of rigid criteria some doctors will find S C A as often as a patient with sickle cells superimposed anæmia, while others, more cautio ascribe to malaria or to hookworms what is n true S C A Between these extreme attitudes t room for much confusion and hesitation

We briefly review here the differential criteria monly used, and describe a new method that has very useful in our laboratory in distinguishing S C A and S C T

Present Status of Differential Diagnosis

Foy and Kondi (1951) have enumerated very ten methods for differentiating between the ana the trait Seven of these methods, however, are ticable under field conditions in Africa working wit laboratory facilities

Four of the suggested methods have no chance of being introduced, even in a better than laboratory or general hospital service

(1) *Difference in the electrophoretic pattern of the hæ in the two conditions*

(2) *Study of birefringence* under the polarising m

(3) *Presence of alkali resistant hæmoglobin in S C A* This test, apart from being technically complicated (it the use of a water bath refrigerated at 20°C), presents disadvantages First, it cannot be applied to babies two years of age, owing to the normal presence of resistant fœtal hæmoglobin (Most of our patients belo this age group) Secondly, it is probable, as suggested Neel (1952), that all gradations exist between the encountered in S C A and those observed in trait-carri normal persons Finally, the test lacks specificity, i may be positive in non related blood disorders.

(4) *Difference in the survival time of transfused erythrocytes* Transfusion experiments cannot be regarded as a procedure In babies they can be executed only by h trained specialists

Another method is still in its experimental stage

(5) *The anti S C A rabbit agglutination test* —The pre tion of a specifically absorbed rabbit serum that aggl S C A erythrocytes seems indeed the ideal approach to problem A serum with such properties has been prep Schneider and Levin (1950) but it gives such weak that its use would be of little help under field cond Repeated efforts to prepare a similar reagent have entirely unsuccessful in our hands

The following two points are of real value in the majority of cases, but may be very misleading in

(6) *The different clinical picture in the two condit* Among the children sent to the laboratory with the note "shows all the typical signs of S C A" a few had no cells at all on repeated examinations. The coincident p of the sickle cell trait in such cases would erroneously led to a diagnosis of S C A In consequence, however doxical it may seem, a syndrome with the clinical fea S C A in a patient with sickle cells is not necessarily true S C On the other hand, babies and infants affected with S do not always have clinical symptoms, and we have de several cases while making routine blood examinations other purposes It is our experience that babies ra manifest clinical symptoms of S C A during the fir months of life If we admit, as stated above, that S C A congenital anomaly, genetically determined at birth, we m agree that there is a preclinical stage of the disease, and question can be raised as to whether diagnosis is pos without waiting for gross clinical and hæmatol manifestations

(7) *The failure of S C A to respond to any form of treatment* We agree that there is no lasting treatment for S C A, but does not discount the fact that several of our little pa treated with small repeated transfusions and common portive medication left the wards completely anicteric, satisfactory hæmoglobin levels and normal reticul counts In such cases the passage of time will show that improvement was not definitive, but diagnosis should made on admission and not after a prolonged follow up

he three remaining points in the enumeration of r and Kondi (1951) are of incontestable value in erential diagnosis

) *The lower percentage of sickling that occurs in S C A at ced pressures in the Thunberg tube*—This test has been lied by Sherman (1940) to a few cases with very clear-cut ults. Recently however Lange et al (1951) repeated the erimental work of Sherman under better-controlled litions and reached the conclusion that the sharp differen ion between cells from the anæmia and the trait could not ays be made by this technique alone The same over ping of results occurs in the determination of the degree of ling in vivo using the anaerobic venepuncture method rman 1940) Results obtained by these techniques are y significant when they fall into two extreme categories ermediate values are occasionally recorded which require eful interpretation

9) *The presence of sickle cells in stained films of the peripheral d in the anæmic state*—It is well known that sickle cells 17 be present in the stained dry smears of patients with A., despite the inevitable exposure of the blood to atmos ric oxygen (Diggs and Bibb 1939) They are never seen he trait condition; their presence is therefore a simple safe criterion of S.C.A. These "irreversibly sickled cells also recognisable on *immediate* examination of a wet paration of finger prick or venous blood Unhappily this is not constant, and in some cases repeated examination fail to detect a single "irreversibly" sickled cell

10) *The appearance of long filamentous processes in S C A r twelve hours' incubation at 37°C and their absence in the t condition*—We have checked this test in 150 cases of A and several hundred people with the trait and we nd it an extremely reliable tool for differential diagnosis tle cells of the filamentous type were found in all our cases C.A immediately on admission, and a tentative diagnosis ld have been made on this ground alone (Vandepitte 1952 ndepitte and Pieters 1952) American workers independently hed the same conclusion as Foy and Kondi (Neel 1951) filamentous aspect, however is less obvious during the escent periods of the disease and may be entirely obscured repeated transfusions Furthermore this sign may be ative for several weeks or months after birth when only nall percentage of red cells can be induced to sickle even other methods involving the use of strong reducing agents. me of our babies we saw the reversal from the "compact" the "filamentous type of sickling at about the age of months At that time a moderate anæmia was the only ptom, but the diagnosis of S C.A was evident from other thods Another drawback of this method is that trait cells patients with anæmia of other origin, particularly of the ochromic type may also tend to form numerous but finer d shorter appendages Considerable experience and several preparations may be necessary to clarify the diagnosis.

The enumeration of Foy and Kondi (1951) takes no ount of the corroborative evidence offered by the nonstration of sickle cells in both parents. As S C.A. now considered as a homozygous condition it cannot at when one of the parents lacks the sickle-cell omaly It must, however be realised that a few ceptions to this rule can occur: other hæmoglobin omalies—e.g Cooley's trait and the newly described æmoglobin III'—genetically combined with S C T y produce a mild form of hæmolytic anæmia closely nulating S C.A. The present status of this interesting blem has been reviewed by Neel (1952) In our 150 es of S C A only one mother was negative for sickle ls. More exceptions were found among the fathers, t in most instances it was easy to show that the legal her was not the biological father In conclusion, S C.A. very unlikely in a patient whose mother shows no kling when a reliable technique is used

From this brief and incomplete discussion of diagnostic ssibilities it is clear that the doctor in Central rica must rely on careful clinical and hæmatological servations and the results of the last two methods. is combination gave us a clear-cut answer in the at majority of cases Difficulties were, however met very young babies with subtle symptomatology in tients admitted between hæmolytic attacks and in patients who had recently received a blood transfusion In these cases the laboratory data may often be summarised as follows "no sickle cells on the dry smear sickling of an elongated but not typically filamentous type in the moist-chamber method moderate anæmia without icterus; reticulocyte-count slightly raised and occasional nucleated erythrocytes in the peripheral blood" It is in such equivocal cases that a simple and more sensitive test applicable under primitive conditions, is needed for exact differential diagnosis.

New Test Using Bone marrow

As the presence of irreversibly sickled erythrocytes (I.S.E) is the simplest and most specific criterion for the diagnosis of S C.A., we hoped that large numbers of such cells would be found in the bone marrow even when they were not observed in the dry smear or on immediate scrutiny of a wet preparation of the peripheral blood Our hope seemed warranted by previous observations:

Diggs and Bibb (1939) reported 3 patients who had no sickled forms in the dry smears of their blood yet had typical sickle cells which would not become round on exposure to air in their pleural or ascitic fluid

Shen et al (1949) proved experimentally that the persistently sickled form had been assumed because of prolonged or repeated intermittent exposure to anoxia in the capillaries of various organs

The bone marrow with its slow circulation and high oxygen uptake, combines ideal conditions for the production of I.S.E and offers the unique advantage of easy accessibility Moreover we were interested in determining whether the distinction between the "compact" and filamentous' types of sickling would not be sharper when the blood withdrawn with the marrow was examined as a sealed moist preparation

A preliminary trial was made on 2 children with well established S C.A. marrow was taken by tibial puncture and wet sealed preparations were made between slide and cover slip and examined without delay under the dry high power objective of the microscope 2 children with the combination of S C T and anæmia of other origin served as controls. Our first impressions were rather deceptive the marrow with its high content of young and actively growing cells acted as a strong reducing agent on the red blood cells and, when preparations were inspected a few minutes after the marrow had been aspirated a variable degree of sickling was already apparent, even if the patient had only S C.T This rendered it very difficult to recognise with certainty a pre-existing sickle cell among the forms that sickled as a result of the rapid exhaustion of free oxygen from the preparation. Here as in the blood, only the sickle cells of S C.A formed the long filamentous processes after sufficient incubation. The aspect of sickle cells in the S C.T marrow did not differ from that observed in the peripheral blood of the same patient. The distinction between the two types of sickling was in no way more clear-cut than in preparations of the peripheral blood

This trial was almost abandoned, when we were suddenly struck by a bizarre picture found in a small grain of myeloid tissue from 1 of the patients with S C A Several microscopical fields were occupied by an irregular entanglement of numerous rod like structures showing the same refraction colour and transparency as the sickle cells. The whole looked somewhat like a dense mycelium which had been artificially broken into smaller branches 1–3 μ wide of various forms and lengths The individual elements varied from bits of a few microns to filaments as long as 50 μ. Vacuolated areas and fusiform swellings were noted Most of the rods were definitely incurved and seemed to follow the contours of the marrow-cells between which they were inserted Others were sharply bent at various angles like broken matches Fig 1 displays these characteristics A closer examination of the preparations from the 2 S C A. patients revealed

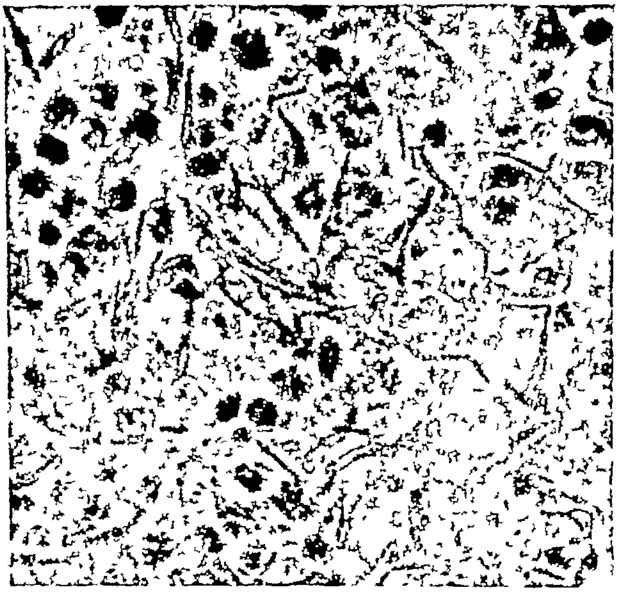

Fig 1—Wet preparation of freshly aspirated marrow from a child with sickle-cell anæmia. Note mycelium like arrangement of hæmoglobin filaments.

other marrow particles containing identical structures Between these particles, in the areas where adult erythrocytes far outnumbered the scattered nucleated cells, some rare rods could be seen floating freely between the cells Their number increased significantly in the neighbourhood of the marrow particles, giving the impression that they had been detached or broken off from the mycelium-like masses in the course of diverse manipulations The morphology of isolated and grouped filaments was not visibly influenced by incubation of the sealed preparation, and the filaments remained unaffected by the progress of sickling No such structures were discovered in the preparations of the controls, even after long examination

The study of the wet marrow film disclosed such neat differences between S C A and S C T subjects that further trials seemed justified We had to verify whether marrow puncture could be introduced as a routine procedure for differential diagnosis between the two conditions

TECHNIQUE

In babies and infants a little marrow, variably diluted with blood, was aspirated by puncture of the proximal end of the tibia In older persons the sternum was preferred The marrow fluid was expelled on to a microscope slide or a watch glass With the edge of a cover slip the solid marrow particles were carefully selected and transferred to a clean slide By a gentle slipping movement the material was spread between slide and cover glass, on which pressure was momentarily exerted to extrude excess blood and to produce a marrow film sufficiently thin to permit satisfactory examination The preparations were sealed with melted paraffin and immediately inspected under the dry high power objective At least three wet preparations were made in this manner for each patient

The "wet marrow test" was reported as ++ positive when one or more of the above described masses of filaments were noted, + positive when only occasional hæmoglobin rods were found scattered among the erythrocytes or enclosed in a marrow grain, and negative when no such structures were detected in the three wet films All the persons included in this study were also subjected to the following examinations erythrocytes and leucocytes per c mm, hæmoglobin g per 100 ml, and differential leucocyte, nucleated red-cell, reticulocyte counts When venepuncture was the percentage of in-vivo sickling and the serum [illegible] level were determined

MATERIAL

We studied 44 patients classified, for convenience four categories

Group I consisted of 15 patients in whom the disease active S C A was firmly established All were [illegible] and showed a frank filamentous type of sickling 6 of had typical sickle cells on a Giemsa stained dry smear ages ranged from two months to seventeen years [illegible] recently been admitted to the hospital and had never transfused

Group II was composed of 12 patients having S.C.T imposed upon another anæmia 2 of them were adu[illegible] megaloblastic marrow picture, and the remainder infants with a hypochromic anæmia due to [illegible] infestation and/or malaria

Group III contained 12 patients in whom S C.A had diagnosed on admission During a period of at least weeks they had been *transfused repeatedly* with comp blood and had also received parenteral liver, folic acid, B_{12}, and iron Under this therapy the characteristic logical features of S C A had been masked to various de filamentous sickling was discrete and sometimes diff discern

Group IV consisted of 5 siblings of S C A patients were not considered ill by their parents, but their pictures showed various signs suggesting S C A [illegible] anæmia with polychromatophilia, increased reticulocyte leucocyte counts, and a tendency to the filamentous ty sickling The preclinical stage of S C.A was therefore suspected

RESULTS

The results of the marrow examination are summa in the accompanying table In the patients with

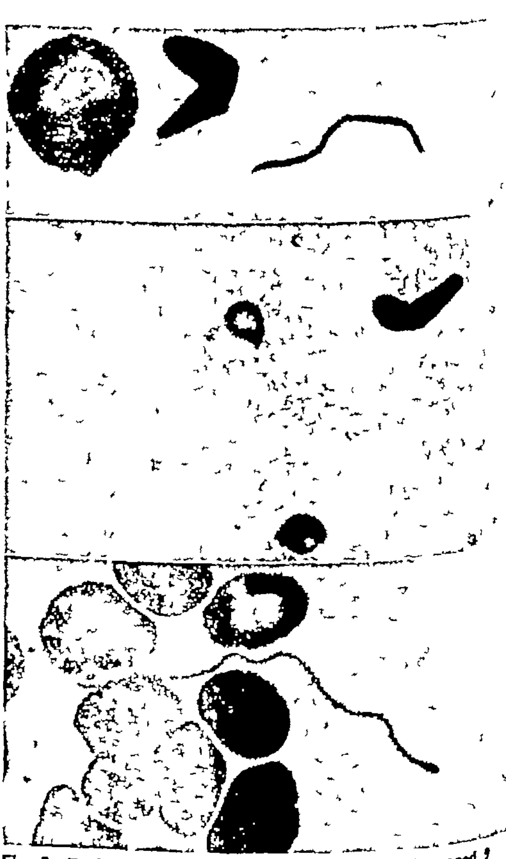

Fig 2—Eosin-stained thin blood-smear from baby aged with sickle-cell anæmia. Note mechanical fragmentatio irreversibly sickled red cells.

RESULTS OF WET MARROW TEST IN 44 PATIENTS

Group	No of patients tested	Wet marrow test			No. of patients with sickle cells on dry smear
		+ +	+	–	
tive S.C.A	15	13	2	0	6
C.T with other anæmia	12	0	0	12	0
reated S.C.A	12	10	0	2	4
reclinical S.C.A	5	5	0	0	0

A a positive wet marrow test was always found ther with the filamentous type of sickling in the pheral blood Differences in the aspect of the sickle , however are to some degree quantitative and a ter of subjective appreciation Therefore it is easily erstood that a more quantitative test, giving a r-cut all or none result, will be preferred by the less erienced worker The new wet marrow test fulfils demand Neither age nor sex of the patient, nor the rity of the anæmia, seemed to influence the degree ositivity of the marrow picture A strongly positive was noted in a patient with a red-cell count of more 1 4 000,000 yet showing the typical joint pains of On the other hand, the 2 weakly positive results table) were observed in very anæmic patients. The results were obtained when large and numerous row particles could be aspirated and inspected It be worthy of note that a strongly positive wet row test was obtained from the 1 S.C.A patient in series whose mother was a non sickler Also in other ects there was no reason to admit that this case was severe than the classical S.C.A as seen in homozygous ects. The question therefore remains open whether patient was heterozygous or, as a result of mutation ozygous for his sickle-cell gene

ur work emphasises the difficulty met with in nosing S.C.A in patients who have been recently and atedly transfused Of the 12 S.C.A patients belonging his category only 5 exhibited typical filamentous le cells the remainder giving equivocal readings, after prolonged incubation of the wet blood film examination of the wet marrow aspirate produced lence of S.C.A. in 10 of those cases. In the 2 others, e of the hæmatological findings pointed towards the ibility of S.C.A although its existence had been ly established a few weeks before Such diagnostic culties are only avoidable when every Negro patient, spective of his complaints, is screened for the sickling lency of his blood within the first hours of his hospital ission

he superiority of the wet marrow test was best ealed by its application to children with preclinical The youngest patient in this group was only n weeks old and apparently in perfect health It be interesting to apply the new method to younger les and it is conceivable that positive results will be d in the newborn S.C.A may also exist in a latent n in older children; a positive wet marrow test was d in an apparently normal girl of more than five rs Her blood picture, however was compatible with existence of a well-compensated anæmia of the nolytic type

Discussion

he microscopical picture offered by a positive wet row test is so conspicuous and so impressive that one wonder that it has not been described before. This t chiefly be attributed to the failure of previous kers to examine wet films of their marrow aspirates. have found one published reference of such examina but only the enhancement of the sickling progress noted (Singer and Robin 1948) Although dozens of kers have examined stained dry marrow films of their A patients only very few noted abnormalities that ht be related to the impressive picture regularly observable in wet specimens In several bone-marrow smears from patients with S.C.A Wintrobe (1951) saw some very long filamentous bands of what appeared to him erythrocyte cytoplasm Many years before him Sydenstricker et al (1923) had made the same discovery on necropsy material of a child with S.C.A. We had no difficulty in finding the same filaments in the *stained* marrow smears of our cases; but they were never so conspicuous as in the wet film and it was exceptional to find two or three of them together in the same microscopical field The enormous advantage of the wet marrow film for diagnosis can be easily explained on purely technical grounds The quantity of marrow aspirate necessary for a dry film is only a minute fraction of what can be rapidly inspected in a wet preparation In addition the delicate mycelium like arrangement of the hæmoglobin filaments is disrupted in spreading the film, and only widely scattered and rather amorphous debris is left.

Although our work was primarily undertaken to demonstrate a new diagnostic difference between anæmia *and trait cells, our findings also shed new light on the* disintegration of red cells in S.C.A A few years ago no satisfactory explanation could be given for the difference between the survival time of anæmia and trait erythrocytes Some workers found it conceivable that an additional structural alteration different from the sickling tendency might be operating in the production of S.C.A (Singer et al. 1948) We have now additional evidence that the different behaviour of trait and anæmia erythrocytes can be satisfactorily explained by the morphological differences in their actual sickle shape It has been repeatedly emphasised that only a very small percentage of trait cells assume the sickle shape within the circulation and as those sickle cells are only slightly incurved and not significantly elongated it is admissible that their mechanical *fragility in vivo remains* unaltered Disintegration of trait cells is therefore not accelerated beyond the normal rhythm of erythrocyte decay By contrast in patients with S.C.A an important proportion of erythrocytes circulate in the sickled form and as they carry about a double dose of the abnormal hæmoglobin they take on a definitely elongated crescent shape and develop long rigid processes These brittle needle like filaments are continuously broken off during the passage in the narrow capillaries of different organs. Fig 2 shows successive phases of the mechanical erythrocyte disintegration seen in the peripheral blood of a nine-week-old baby with severe S.C.A

Our findings in the marrow of S.C.A patients reinforce the opinion that mechanical factors have a preponderant rôle in the pathogenesis of the hæmolytic process. When sickle cells of the filamentous type pass through the venous sinusoids of the bone marrow their sharply pointed ends may slip through the small openings between the lining cells of the endothelial wall Once they have left the vascular bed these erythrocytes are caught in the interstices of the marrow stroma where they cannot be perfused out. In this highly cellular environment the abnormal hæmoglobin is further reduced and undergoes a maximal crystallisation provoking the extreme and irreversible deformations of the red blood-cells. The ultimate fate of these trapped hæmoglobin bands is probably lysis and phagocytosis. More information on their exact localisation will probably be provided by serial sections of fixed bone marrow Our hypothesis could further be tested by transfusing massive doses *of S.C.A blood into normal recipients. If our inter*pretation is correct the abnormally short survival time of the transfused red blood-cells should be reflected by the appearance in the recipient's marrow of the typical hæmoglobin filaments

Our work favours the view that the bone marrow takes a part in the blood destruction of S.C.A although this part may be qualitatively rather unimportant It is, however, probable that the same mechanism of selective filtering and trapping of sickled erythrocytes may be operating in other organs of the reticulo endothelial system

Summary

The differential diagnosis between sickle cell anæmia (S C A.) and anæmia of other origin grafted on to sickle cell trait is of first importance in Central Africa When laboratory facilities are not available, much information can be gained by simple inspection of the stained thin blood-smear, and of the sickle-cells after overnight incubation using the standard moist-chamber method The practical value of the latter method was substantiated by its successful use in over 150 cases of S C A at Leopoldville The test is of limited value in transfused patients and in the preclinical disease

Examination of wet marrow films of S C A patients revealed bizarre formations made up of numerous hæmoglobin filaments These were so constantly absent from the marrow of persons with sickle cell trait that their presence may be accepted as a safe and sensitive criterion of sickle cell anæmia The only failures of this new method were noted in two S C A patients who had received repeated transfusions

Some theoretical implication of these findings are considered, and a mechanical explanation of the blood destruction in S C A is briefly presented

We wish to thank the team of doctors who selected the patients for this study, especially Dr F Périn of the Government Hospital

PERFORATED DUODENAL ULCER IN CHILDREN

D MILLAR BELL
M.B Belf, F.R C.S, F.R C S.E
SENIOR SURGICAL REGISTRAR, ST BARTHOLOMEW'S HOSPITAL, ROCHESTER, KENT

PEPTIC ulceration in children is relatively uncommon Hutchins (1944) found that only 243 cases of peptic ulceration in infants and children had been reported, and only 77 cases of perforated peptic ulcer 2 further cases of perforated duodenal ulcer are described here

CASE-RECORDS

Case 1 —A boy, aged 5 years, was admitted on July 8, 1952, having had pain in the centre of his abdomen from 5 P.M the previous evening, which had kept him awake during the night He had felt sick but did not vomit On the day of admission the pain had persisted and had spread to the right iliac fossa He had no other symptoms His temperature on admission was 100 4°F

He had been in hospital three months previously with similar but less severe pain, and had been kept under observation for five days He had otherwise bee healthy child, except for influenza at the age of 2½

On examination he was well nourished and lo His tongue was moist and had a greyish white coat glands were palpable in his neck. His abdomen m with respiration There was tenderness in the rig fossa, but no rebound pain was elicited and no felt The tender zone in the right iliac fossa to the level of the anterior superior iliac spine Th no tenderness on rectal examination The both acute appendicitis and mesenteric adenitis.

Operation —With the child under general anæs made a right gridiron incision and found turbid fluid peritoneal cavity The appendix was retrocæcal but normal A few small mesenteric glands were palpable incision was extended upwards and outwards, and indurated area at the pylorus was then easily This was seen to be the site of a chronic duodenal with a small perforation in the centre, partially by adherent omentum, A search was made for a foreign body, but none was found The perforation closed and the omentum oversewn in the usual way area of induration in the first part of the duodenum for about half an inch

Postoperatively the patient made an uneventful and was discharged from hospital twenty two da operation Plain radiography of the abdomen did not any foreign body in the peritoneal cavity A barium showed considerable scarring of the duodenum, of the gastric mucosa, and what appeared to be an the lesser curve of the pars media

Case 2 —A girl, aged 5 years, was admitted to the Hospital for Sick Children on Oct 22, 1945 Her previous illness was measles There had been no dyspeptic symptoms On the day before admission the day of admission she had complained to her "crampy pains in the stomach" She was at school day of admission to hospital, and had vomited once the same evening she was walking along the road w parents, when she vomited again and said that the her stomach was worse About two or three hours she was admitted to hospital Her appetite was good up to the onset of symptoms she had had no urinary and her bowels were regular

On examination she looked healthy Her abdomen but little with respiration, especially the lower part palpation there was rigidity of the lower abdomen, marked on the right side The upper abdomen was rigid nor tender There was tenderness in both iliac more severe in the right On rectal examination slight tenderness on the right side There were no constituents in the urine The child said that the been all over her stomach at first but was now in the side only Acute appendicitis was diagnosed

Operation —With the child under general opened the abdomen through a right-gridiron incision found the appendix normal, but clear free fluid, with fragments of peas, escaped through the wound. incision was extended upwards and a perforation of anterior duodenal wall was found No induration the perforation. The perforation was closed with sutures, and the peritoneal cavity aspirated

Postoperative Course —The patient's general condi good throughout the operation, her temperature 101 8°F on the day after the operation, but subs 99°F in the next twelve hours She made an une recovery and was discharged on the fifteenth day

DISCUSSION

Since Hutchins's (1944) report 13 more cases been collected in the past ten years (Spencer Rogerson 1951) Proctor (1925) found 2 children necropsies in ulcer cases at the Mayo Clinic in 1 Ladd and Gross (1941) have analysed the cases and have drawn the following conclusions

(1) Ulcers are more common in infancy, and least in children aged 2–7 years.

(2) Ulcers in infancy are more likely to bleed and forate, whereas ulcers in later childhood are more perforate and to cause stenosis.

2 present cases seem to be in agreement with the rvation about perforation

no diagnosis of perforated peptic ulcer was not ght of in these cases. Further questioning after the ation did not elicit any definite previous history of r in either case.

he sharp contrast between the 2 present cases and s of perforated peptic ulcer in adults is most inter g In adults generalised abdominal rigidity is usually d in association with severe abdominal pain of len onset In neither of the present cases did the seem severe and there was no generalised rigidity ther case 1 was characteristic of perforation of a nic ulcer, whereas case 2 was characteristic of oration of an acute ulcer

wish to thank Mr Ian Fraser and Mr S M Cohen for ission to publish these cases and Dr J M Corall for the graphic examination.

A TRAUMATIC HÆMOTHORAX

RICHARD BATTEN
F.R C.S.

ATE RESIDENT SURGICAL OFFICER, COUNTY HOSPITAL,
HEREFORD

ÆMOTHORAX is seldom seen in civilian practice, and n it does occur is usually caused by broken ribs he following case it was an uncommon sequel to a mon accident

CASE RECORD

healthy boy aged 11 was climbing a tree, when he fell ugh the branches about 40 ft to the ground On being ed up he was a little dyspnœic but quite conscious. He taken to a nearby hospital, where he was found to have a rficial laceration of the left lower abdominal wall; he also eared to have fractured lower ribs on the left side one of h was distorting the skin. The laceration was sutured with e stitches and the boy was given anti tetanus serum. to bed, and given penicillin 400 000 units daily

uring the next two days his temperature remained raised 01°F and his left chest became dull to percussion On the d day he was transferred to the County Hospital Hereford er the care of Mr F Brian Thomas.

n admission the laceration in the boy s lower abdomen healing well His apex beat was in the 5th interspace to the right of the sternum and the whole of the left side his chest was dull to percussion I could not confirm the ence of fractured ribs, however and asked for radiographs. o confirmed the presence of fluid with a small apical umothorax but showed no fracture.

reatment and Progress —*Aspiration with a wide-bore needle* duced only a small cylindrical clot, and it was concluded t he must have a coagulated hæmothorax. Penicillin ,000 *units was given six hourly Except for his injections* boy was comfortable though slightly dyspnœic. He was dly pyrexial but otherwise in good condition, and the air ry in his left lung increased a little as the pneumothorax absorbed

On the seventeenth day after the accident the boy com ined of a pain in his back. There was a hot red swelling h a pale fluctuant centre below the angle of the left pula. Deep to this a hard resistance was felt which led to believe that exuberant callus was forming round a viously undetected fracture of a rib Radiography again wed an undamaged thoracic cage and the abscess aspirated. A little pus was obtained and sent for ture but the point of the needle met a harder object When agment of skin was removed over the centre of the abscess, oreign body resembling a small spicule of wood was seen. ing to the surrounding inflammation and the hæmothorax ther local nor inhalation anæsthesia seemed suitable for its oval A poultice was applied with a protective ring sing to keep pressure from the site No scar was found on chest through which the wooden splinter if such it were, ld have entered

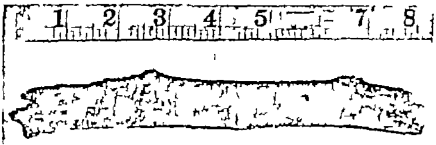

Fig 1—Broken stick of cherry wood $8^1/_2$ in. long and 1 in. in diameter which entered patient's thorax.

Next day the pus was reported to contain *Clostridium welchii* (later proved to be penicillin sensitive) and coliform bacilli

Removal of Foreign Body —Mr Brian Thomas inspected the abscess, which now showed quite clearly a fragment of wood He applied a stout pair of forceps to its end and with a steady pull extracted a broken stick of cherry wood $8^1/_2$ in. long and 1 in in diameter (fig 1)

Subsequent Progress —The patient said he felt much better for this operation, which was at once followed by a slight sucking pneumothorax controlled by a large wet pack. *During the next three days a large amount of serous exudate* drained from the thorax, and the boy recovered steadily Radiography now showed good re-expansion in the left lung and for the first time a visible track rising from the apex of the tented left dia phragm (fig 2) The wound in the back con tinued for some time longer to discharge small quantities of serous exudate in which a piece of check shirt material and a fragment of flannel trouser were found. The patient made an uninterrupted recovery in hos pital the re expansion of his lung being en couraged by seg mental breathing exercises He remained up and about during *this period and on one* occasion he tracked me to my room demanding to see his stick He looked at it for a minute exclaimed Coo what a whopper! *and was gone delighted*

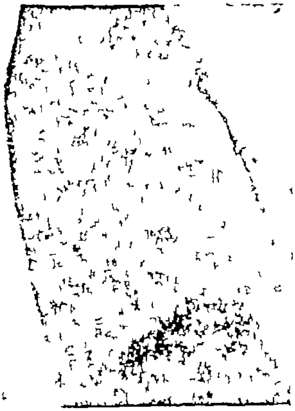

Fig 2—Radiograph of left lung soon after removal of foreign body

Follow up —Three months after discharge from hospital he was in excellent health, with a healed chest wound and radiologically normal lung and diaphragm and was playing football for his school

CONCLUSIONS

The only wound on admission was the linear laceration $2^1/_2$ in long in the anterior abdominal wall, level with the anterior superior iliac spine and 1 in. to the left of the midline The piece of wood must have entered here traversed the abdomen missing intestine stomach and spleen to perforate the *left dome of the diaphragm* It must then have transfixed the left lung missing the heart, and presented between the sixth and seventh ribs posteriorly mimicking a fractured rib, though no rib was damaged

The *Cl welchii* responsible for the infection was still alive after seventeen days' treatment with penicillin, to which it was sensitive Little of the antibiotic may have reached the centre of the hæmothorax, and the coliforms present may have inactivated that which did

The infection was responsible for the clotting of the hæmothorax

The wood must have had exactly the same radiotranslucency as blood, since the most careful subsequent scrutiny failed to show its presence in the chest radiographs

The young human organism possesses remarkable resilience to even dramatic traumata of bacterial, dynamic, and structural types

SUMMARY

A piece of wood $8^1/_2$ in long and 1 in in diameter passed through a boy's abdomen into the left side of his thorax without damaging any abdominal viscus, the heart, or ribs The boy recovered completely after the stick had been removed

I am indebted to Dr Cameron Gibson who first attended this patient, and to Mr F Brian Thomas, under whose care he was at the County Hospital, Hereford, for permission to publish

Preliminary Communication

INFLUENCE OF PHENYLALANINE INTAKE ON PHENYLKETONURIA

In phenylketonuria phenylalanine accumulates in the blood and cerebrospinal fluid, probably because phenylalanine is not converted to a normal extent into tyrosine On the assumption that this excessive concentration of phenylalanine (or perhaps of some breakdown product) is responsible for the mental retardation found in this condition we decided to keep a girl, aged 2 years, with phenylketonuria on a diet low in phenylalanine She was an idiot and unable to stand, walk, or talk, she showed no interest in her food or surroundings, and spent her time groaning crying, and banging her head The diet had to be specially prepared, because a sufficiently low phenylalanine intake could only be attained by restricting practically all the nitrogen intake to a special casein (acid) hydrolysate (Allen & Hanburys Ltd) This was treated with activated acid-washed charcoal, which removed phenylalanine and tyrosine Tyrosine, tryptophane, and cystine were then added in suitable amounts

RESPONSE TO LOW-PHENYLALANINE DIET

The child was at first treated in hospital so that careful observation could be made During a four-week preliminary period, when no phenylalanine was permitted, no definite clinical change other than loss of weight was observed The characteristic musty smell disappeared, the levels of phenylalanine in plasma and urine fell to normal, the excretion of phenylpyruvic acid ceased, and the ferric chloride reaction became negative (see figure)

Subsequently, presumably as the result of tissue breakdown, the biochemical abnormalities returned to some extent, along with a generalised amino aciduria Phenylalanine was therefore added in small amounts in the form of whole milk, a daily intake of 0 3-0 5 g being found sufficient for normal weight gain with greatly improved biochemical findings

During continued outpatient treatment a improvement in the child's mental state took within the next few months she learnt to crawl, and to climb on chairs, her eyes became bright hair grew darker, and she no longer banged her or cried continuously

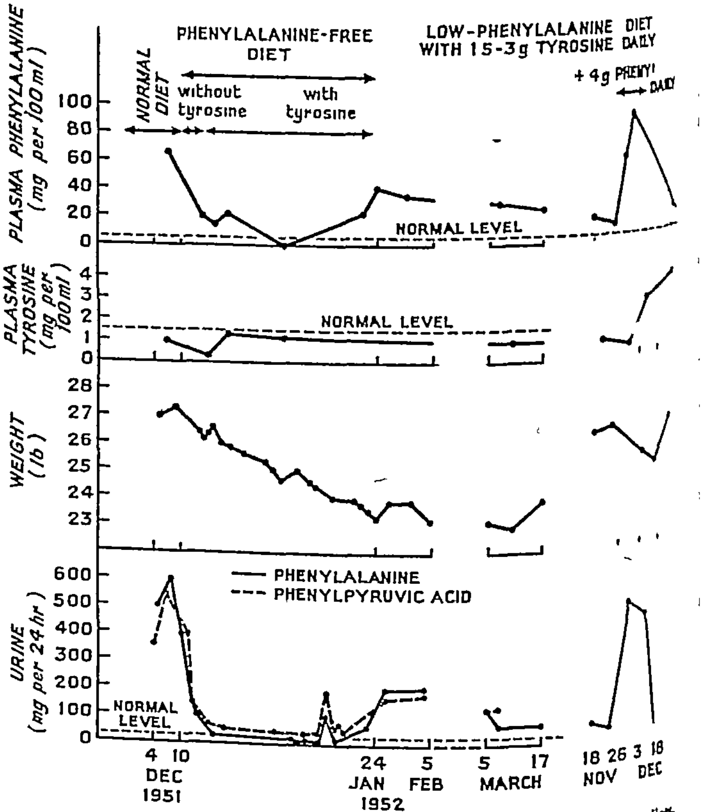
The most suitable diet so far evolved conta source of amino acids only the special hy vegetables and fruit, gluten-free bread and flour freely permitted

RESPONSE TO ADDITIONAL PHENYLALANINE IN

In view of the importance of establishing the clinical improvement noted (which depend first largely on the observation of the mother) w and due to the diet rather than to natural develo we decided to add L phenylalanine 5 g daily t diet This was added to the hydrolysate without mother's knowledge, so that any change shoul noted without bias

A definite deterioration in the child's condition the mother reporting with distress that her d had lost in a few days all the ground gained previous ten months, that within six hours of the fresh supply of "food" the child had begun and to bang her head as in the past, and within four hours could no longer stand and could crawl

In view of the importance of obtaining ad proof of the value of the special diet, at present



Biochemical reactions to phenylalanine-free and to low-phenylalanine diet

expensive, the mother agreed to a further similar in hospital, which permitted close correlation of c and biochemical findings and cinematographic r After a period of observation on a low phenyl diet, L phenylalanine 4 g daily was again added to diet Within twenty-four hours the patient b irritable and drowsy, lost interest in her food oundings, developed facial eczema, and salivated fusely She also became ataxic and vomited repeat- By the sixth day she could no longer stand or The additional phenylalanine was then discon ed and within three weeks she had almost completely vered.

BIOCHEMICAL FINDINGS

Vhen phenylalanine was added to the diet, the ma phenylalanine level rose from 13 to 91 mg per ml, and the urinary excretion of this amino acid eased from 40 to 500 mg per 24 hr (see figure and le) Two weeks after the extra phenylalanine had n discontinued the urinary excretion of this amino d decreased *to 20 mg per 24 hr and the plasma* nylalanine level fell during the next few weeks to and then to 19 5 mg per 100 ml, and is now normal mg per 100 ml) The ferric-chloride test, which negative with the low phenylalanine diet gave lack green reaction while the child was receiving a phenylalanine

NYLALANINE AND TYROSINE LEVELS IN A PHENYLKETO URIC PATIENT AND IN A CONTROL BEFORE AND DURING PHENYLALANINE FEEDING EXPERIMENT

—	Phenylketonuric patient		Normal control	
	Phenyl alanine	Tyrosine	Phenyl alanine	Tyrosine
plasma (mg per 100 ml)				
fore phenylalanine feeding	13·0	0 7	1 1	1 7
uring feeding of L-phenylalanine 4 g daily	90 5	·7	6 1	2 0
rine (mg per 24 hr)				
fore phenylalanine feeding	40	5 3	4 2	6 4
uring feeding of L-phenylalanine 4 g daily	500	14 0	[illegible]00	11 0

On a diet low in phenylalanine.

Ve have also given phenylalanine (14 g in four days) normal infant, aged 5 months, without producing change in behaviour or any comparable rise in the ma phenylalanine level which did not exceed 6 1 mg 100 ml. (see table)

hese findings suggest that high levels of phenylalanine of its breakdown products disturb cerebral functions may possibly give rise to the mental retardation found henylketonurics

CONCLUSION

n this child at least the beneficial effects of a low nylalanine intake seem unequivocal although the ree of mental development finally obtained remains be seen after further prolonged treatment. In view he importance of phenylketonuria as a cause of mental ciency further controlled trials are being made, cial attention being paid to very young children, who likely to benefit most.

Ve gratefully acknowledge the help and interest of Dr O. Smallwood Prof J M. Smellie and Prof J R dre Dr L. I Woolf first drew our attention to the nique of removing phenylalanine from casein hydrolysate gave further valuable assistance Messrs Allen & burys Ltd have recently presented us with a supply of nylalanine free casein hydrolysate

he methods employed will be described in a fuller account o published in *Acta pædiatrica*

Reviews of Books

William Cheselden, 1688–1752

SIR ZACHARY COPE, M.D M.S., F R.C.S., consulting surgeon St Mary s Hospital London Edinburgh: E & S Livingstone 1953 Pp 112 20s.

Cheselden was the foremost surgeon of his time and in this lively and well illustrated book Sir Zachary Cope has provided him with a worthy biography

Cheselden retired from the staff of St Thomas s Hospital before Percival Pott was elected to the staff of St Bartholomew's Hospital His general surgical ability was great his ophthalmic work enterprising and in some respects original and his speed and success in cutting for the stone had no equal *in pre-anæsthetic days. But he achieved something* more than this and something greater and more lasting for his technical skill died with him He was the first man in this country who insisted on the importance of a sound knowledge of anatomy for the medical student and upon dissection for a knowledge of anatomy He was the first regular and recognised teacher of anatomy in Great Britain There had indeed been courses of anatomy before his time but none which continued regularly with a printed syllabus and a companion textbook which became so popular that it maintained its place for more than a century

Sir Zachary shows him in many guises. We are shown the lithotomist gradually evolving his own technique. We see him as the architect of the old Fulham (or Putney) Bridge—a wooden memorial which withstood heavy traffic for 150 years. We see him as a teacher instructing among others, John Hunter We see him as a superb draughtsman his *Osteographia* has lived because of the beauty and accuracy of the pictures he drew for its text was far less satisfying We see him as a negotiator responsible more than anyone else for separating the Surgeons from the Barbers

British Medical Science and Practice

An anthology Editor: G F PETRIE M D London: Longmans, Green 1953 Pp 172 15s

THIS anthology has been sponsored by the British Council with the object of helping doctors and students abroad to follow modern trends of medicine as it is practised in Britain It might be thought that such a compilation would be scrappy but this interesting and impressive collection well illustrated well printed and well arranged is a credit to its editor and publishers.

The introductory section briefly surveys some of the landmarks in British medical history as illustrated in the work of ten pioneers—Harvey Hunter Jenner Bell Bright Addison Simpson, Florence Nightingale Lister and Manson. The character of each is portrayed through excerpts taken from their own writings and from standard biographies. The small selection of aphorisms ranges from the 17th to the 20th centuries. The only living contributor Geoffrey Keynes holds his own in distinguished company with three apt aphorisms—for example Speed in a surgical operation depends not on quick movements but on the absence of unnecessary movements. The third and main part of the anthology deals with present-day medical science and rightly fills three-quarters of the book Extracts of up to 500 words have been chosen from articles by distinguished authorities in almost every branch of medicine An appendix gives the qualifications and experience of the contributors

Ciba Foundation Colloquia on Endocrinology

Vol 6. *Hormonal factors in carbohydrate metabolism* Editor: G E. W WOLSTENHOLME, O.B.E. M.A M.B assisted by JESSIE S FREEMAN London: J & A. Churchill 1953 Pp 350 35s

MOST of us have had trouble with the management of diabetes and our difficulties are not all explained by poor coöperation from the patient; nor will they all be resolved by newer types of insulin This engaging volume shows why each diabetic is an individual problem It plunges straight into a discussion of alternative pathways of carbohydrate oxidation and thence into localisation of enzyme systems in the liver cell; after which, Dr C H Best F R.S the chairman was driven to exclaim I d like to bring the clinicians into this discussion but I don t know just how to do it." Important papers follow on the interconversion of carbohydrate, protein, and fat, and the influence of pituitary and adrenal hormones on the disposal of ingested carbohydrate These are more obviously related to clinical problems—though the fundamental issues raised in the first group of papers may affect them more decisively in the end The influence of insulin on carbohydrate metabolism is discussed in six papers, one reviewing the evidence that the first action of insulin on carbohydrate metabolism is to facilitate the entrance of extracellular glucose into the cell, with its enzyme systems Finally there are papers on sex hormones, pregnancy, and carbohydrate metabolism

Reports of many conferences give the impression that while those who attended enjoyed a stimulating experience, their deliberations, set down in cold print, hardly deserve permanent record This particular conference was an exception, certainly from a clinician's viewpoint For those unused to enzyme chemistry spoken discussion of the fundamental problems must have been difficult to follow, but in print, to be read at leisure, they at least begin to be comprehensible, and to show some relevance to the spuriously simple problems of clinical diabetes This is just the book to quicken an interest—which has perhaps been dulled by an unending procession of patients—in the mechanism of this fascinating disease

Juvenile Delinquency

J D W PEARCE, M.A, M D, F R C P E, D.P M, physician in charge, department of psychiatry, St Mary's Hospital, London London Cassell 1952 Pp 396 25*s*

THIS book, surveying the whole field of juvenile delinquency, is written for magistrates, probation officers, and other non-medical readers as well as for doctors

Such a broad approach handicaps the author Thus the magistrate will find the section on law too elementary, while the psychiatrist will have a similar criticism of the account of child development Nevertheless Dr Pearce has been fair in his emphasis and he says something to interest everybody The reader who comes completely fresh to the subject may be confused by the many different aspects, especially as they are not always dealt with in sequence Thus we have two pages on "instincts" while the development and modification of instinctual urges is discussed twenty pages later, and the relationship between these instincts and delinquency is considered thirty pages earlier It may of course be argued that delinquency can be studied from so many aspects that a consistent approach is one sided, so whether Dr Pearce's presentation seems commendable or not will depend on personal predilection

This is not a vivid book, but it is honest, unemotional, and comprehensive Although the reader will not be inspired, he will not be misled

Sulphonamides and Antibiotics in Man and Animals

2nd ed J STEWART LAWRENCE, M D Edin, M.R C.P, lecturer, department of occupational health, JOHN FRANCIS, M SC, M R C V S, professor of preventive medicine, University of Queensland Veterinary School, with the assistance of ARNOLD SORSBY, M D, F.R.C S, research professor in ophthalmology, Royal College of Surgeons, and PHILIP G SCOTT, F.R C S, consulting surgeon, E.N T department, Royal Devon and Exeter Hospital London H K Lewis 1953 Pp 482 42*s*

WHEN the first edition appeared seven years ago the only established antibacterial drugs were the sulphonamides Penicillin was still restricted to hospitals, and the other antibiotics now in use were still in the laboratory stage or unknown The new edition includes the sulphonamides, the antibiotics, the sulphones, the thiosemicarbazones, *p* aminosalicylic acid, and isoniazid As in the first edition, the emphasis is mainly on clinical aspects The first part deals with mode of action, chemistry, bacteriology, pharmacology and toxicology, drug resistance and choice of drug in treating a specific infection Then comes a brief description of each drug, followed by the treatment of diseases due to infection, which are classified bacteriologically and regionally The chapters dealing with the veterinary use of antibacterial agents are written by Professor Francis.

This book is intended for the medical or veterinary practitioner who needs a brief, practical, and up-to-date exposition of the subject and it well fulfils this function

Conquest of Plague

A Study of the Evolution of Epidemiology L FABI M D Lond Oxford Clarendon Press 1953. P 42*s*

THIS lengthy book deals, in broad outline, wi age-long evolution of conceptions of the nature of p It ends with a brief account of those recent dis which have at last enabled man, not only to p himself against this most ancient and formid epidemic diseases, but even to cure most of the v It is not a history of plague epidemics nor a sy textbook, but a study of the development of t beliefs about the origin of the malady from th primitive man to the present day

The book is divided into four parts The first des traditional conceptions of the disease The second the work of modern research workers on the nature of The third discusses the effect of the local and distribution of the chief species of rat-fleas upon th of bubonic plague, and the fourth deals with nation international measures of plague prevention Wit discovery of pesticides, sulpha drugs, and antibiotic no longer too optimistic to speak of the conquest o disease The mortality of Indian cases of moderate has been reduced from 75% to 10% or less.

Dr Hirst has an international reputation for into the epidemiology of plague and he has studied disease and its history for fifty years He has an important and well-documented monograph he regards as only an introduction to the subject.

Enzymatic Concept of Anaphylaxis and Allergy

Z Z GODLOWSKI, M D Cracow, PH D Edin. research fellow of the Carnegie Trust, Edi Edinburgh and London. E & S Livingstone. Pp 120 15*s*

IN attempting to formulate an enzymatic conc allergy and anaphylaxis Dr Godlowski has drawn diverse sources which are often difficult to relate to other

In this, and in the deductions from his own ex he has permitted his theoretical concept to colour his pretation of the findings For example, he claims that e phil leucocyte cells can develop, as a result of the changes, not only from myeloid tissue but also from int epithelial cells, whence they migrate into the deeper The opposite possibility, that the eosinophil cells migrated from the blood vessels into the subepithelial epithelial tissues, he dismisses as highly improbable, due consideration of the histological pitfalls which ca from the superimposition of eosinophil granules on othe and from the changing appearance of amœboid m cells due to the pressure of surrounding tissue cells.

In his foreword Professor Drennan disarms cr by admitting that "it may be objected that th more theorising than the facts merit" But Godlowski's colleagues will be stimulated by his ing experiments on the influence of antigenic and d genised diets on circulating and tissue eosinophils on the influence of heparin and cortisone on eos and other white blood-cells

---

Insecticides (H.M Stationery Office 1953 £3)—The committee on insecticides of the World Health Org had the task of establishing specifications for inse to be used against vectors of disease in man, and for spr equipment used in malaria control This strongly b loose leaf volume contains all the specifications esta by the committee in the last four years, and it will be convenience for users of these products, as well as f manufacturers, to have them gathered together in thi Some dozen products are listed here, and there are specifications for spraying and dusting apparatus A include a guide to sampling procedure, weights and and a list of members of the expert committee, and are some 20 pages for notes Additions and amen can be added to the book as they are published, th be forwarded on request to holders of the volume, th of this service being included in the original purchase

THE LANCET

LONDON SATURDAY OCT 17, 1953

The Drug Bill

N the past few years doctors have had less cause n formerly to consider the economics of prescribing far fewer patients have been paying for their dicines Furthermore prices have seldom been ntioned in pharmaceutical advertisements in medical rnals—a policy related apparently, to differences price when the products are sold abroad Before late war panel practitioners were kept informed the cost of their prescribing as compared with the a average, but this practice has not proved sible under the National Health Service owing to delay in pricing occasioned by the vast numbers prescriptions. Yet the need for such information greater than ever before The steady rise in the ion's medicine bill has caused great concern to Ministry of Health, and last week the Minister nted out (see page 820) that the current rate of enditure under this head (£46 300,000 per annum) *prejudicing other urgent developments.*

Whereas at the start of the National Health Service prietary preparations accounted for 24% of the al ingredient cost, in 1952 they accounted for 56% e Ministry has now issued two lists giving the t of some commonly used proprietary preparations d of some *National Formulary* preparations In ny instances the cost of the proprietary preparation ompared with that of the official equivalent, (in cases the prices for the latter include ingredients cost allowance dispensing fee, and container allow ce) Of the 243 proprietary preparations listed the t, compared with that of the equivalent standard paration, is higher in 67 lower in 47 and the same 10, for the remainder no equivalent standard paration is named The proprietary preparations ich are lower in price than the standard drugs lude certain sulphonamides, barbiturates, vitamins, d sex hormones These figures should dispel the pression that nearly all proprietary preparations needlessly expensive and clearly the practitioner n continue to prescribe some well tried proprietary parations without misgiving Though this list y lead to some saving from reduced demands for less well established and more expensive prepara ns, the main saving is likely to come from a general vering of costs through healthy competition between oprietary and official drugs

Proprietary preparations remain important to dical practice and the contributions of the main armaceutical firms should receive proper financial ward. These firms have not only done much to luce the gap between laboratory knowledge and erapeutic application but have also contributed bstantially to basic medical as well as pharmaceutical earch Even the development of palatable and convenient preparations is no negligible service to patient and doctor These contributions to medicine are however, somewhat offset by the excessive multiplication of preparations and by the marketing *of many less desirable products* By any standard, some thousands of proprietary remedies is far too many Some have in their time been useful but have been surpassed by more potent drugs, others, of limited value, have had their sales maintained more by the personality of pharmaceutical representatives or by polychromatic bulletins than by any scientific evidence, some have been based on pharmacological misinterpretations, and a few have been complete impositions Hitherto these preparations have had to be assessed by the busy general practitioner without disinterested guidance except from reports in the medical journals Lately however the Cohen Committee[1] has classified five thousand proprietary preparations placing in categories 5 and 6 drugs which they regarded as not proved to be of therapeutic value —which is, of course by no means the same thing as proved not to be of therapeutic value. This classification should result in appreciable saving, by discouraging the use of these less essential preparations and strengthening the practitioner's hand against overdemanding patients He retains his own freedom of action for he may still prescribe whatever drug he wishes, but if there is evidence of excessive prescribing he may be called on to justify his actions to his colleagues on the local medical committee No doubt the committee will most commonly be considering the *prescription of drugs in categories 5 and 6* but, as Mr G D STEWART shows in his retort (p 833) to our comment[2] on a case lately considered in Northern Ireland, heavy prescribing of even well-established preparations may be very expensive The procedure of justifying prescriptions to the local medical committee provides a proper safeguard for the public purse without, we *believe unreasonably impairing* professional freedom At any rate the decision whether individual freedom shall or shall not be restricted rests primarily with a professional body

No measure however can be effective without the practitioner's willing coöperation Much depends on his attitude to prescribing, and on other pages Dr *HANDFIELD-JONES and Dr BARHAM CARTER* make some sensible suggestions on the right line to take towards the prescribing of placebos As regards costs the Ministry has now set about trying to influence the attitude of the oncoming generation of practitioners the Ministry's chief medical officer has lately addressed to clinical teachers a letter asking them to consider whether more *information on the cost of* prescribing can be included in the curriculum This approach, however cannot show immediate results For the present generation of doctors the way could still be made easier For instance the Pharmacopœia Commission despite the difficulties with which it is obviously faced might sometimes choose official names *that are briefer and more memorable* though perhaps less explanatory (The practitioner can hardly be expected to replace in his mind vitamin B_{12} by the approved name, cyanocobalamin) Then again the increasing number of official booklets on drugs and appliances issued to practitioners points to a need for greater consideration of the doctor's convenience To issue a thick pile of gummed amendment slips for the *National Formulary*, and expect these to be used, is a false economy Up-to date, compact, and well-arranged data on prescribing would do much to prevent waste If proprietary preparations are being prescribed excessively, it is mostly because of the doctor's personal experience and his own and his patient's ingrained habit, and the doctor cannot be expected to forgo his experience and to change his habit unless he is made fully aware of the grounds for such a change Above all, perhaps there is need for continuous instruction of the public which will reduce its pathological appetite for drugs

[2] *Ibid* p 1 7

"Molluscum Pseudocarcinomatosum"

SQUAMOUS carcinoma of the skin was the first tumour to have its histogenesis solidly established—the work of HANNOVER and of THIERSCH has an enduring, if melancholy, memorial in the survival of that unfortunate name, "epithelioma" The chain of discovery of the carcinogens, which runs from POTT through VON VOLKMANN and YAMAGIWA and ICHIKAWA to KENNAWAY, was linked in the first place entirely with squamous carcinoma of the skin The student finds here his best introduction to tumours, for these are the first he learns to recognise with any confidence It is therefore with shock, and some disbelief, that clinicians and pathologists now find that a substantial proportion of lesions which have been termed squamous carcinoma are in fact something quite different

MACCORMAC and SCARFF in 1936[1] described from the Middlesex Hospital ten cases of a lesion they called molluscum sebaceum The lesion was a single nodule, usually on the face, of the size of a small nut, clothed with normal skin except at the summit where there was an adherent scale Microscopically the lesion was a cyst lined by poorly differentiated hyperplastic squamous epithelium, containing keratin, communicating with the surface, and surrounded by an inflammatory exudate Two clinical features were especially noteworthy (1) the lesion grew rapidly to its greatest size in 4–6 weeks, and (2) simple local treatment, even with carbon-dioxide snow alone, was never followed by recurrence This report aroused a good deal of interest, but it is only in the last few years that the condition has been given the attention it deserves

In 1950 ROOK and WHIMSTER[2] published a definitive account of the histology and natural history of the lesion, and MUSSO and GORDON[3] added the vital observation of regression of an untreated lesion, while this year FOURACRES and WHITTICK[4] have clarified and extended the earlier work, and BEARE,[5] with a series of no fewer than 76 cases, has gone far towards establishing the frequency and importance of the disorder The lesion begins with rapid proliferation of a small area of the otherwise normal epidermis, and for a month there is rapid growth of a type indistinguishable from that of a well differentiated squamous carcinoma Local destructive invasion of the superficial dermis,[4] though often doubted, seems to be a definite feature, but the lesion remain delimited, acquiring a characteristic flask soon a large central mass of keratin develop remarks on the almost pathognomonic this mass at biopsy) After 6–8 weeks regression and the highly active squamous epithelium periphery of the lesion settles down to form inactive coating to the central keratin Finally any time up to a year, the plug is discharged remainder of the lesion contracts to form a scar The best treatment is still uncertain remains necessary, for clinically distinction carcinoma is not always possible If either clinician or the pathologist is unfamiliar condit on (and their cooperation is needed for fident diagnosis), complete excision is pro Histological diagnosis depends much on the and size of the whole lesion, and it is not that hitherto many pathologists have failed to nise the lesion when presented, as they usually with a small and perhaps ill-orientated biopsy men In experienced hands a small biopsy suffices for diagnosis Theoretically one might leave the lesion alone, but in practice some will usually be expected, and if well devised ensures more rapid healing and a better scar Nature BEARE claims that shaving the with the surrounding skin and lightly cau base yields adequate material for biopsy and good healing

The true nature of this lesion remains unc Originally it was thought to be of sebaceous but all the recent evidence points to a direct from the epidermis The cycle of rapid growth fol by regression very strongly suggests a virus and the example of molluscum contagiosum show virus infection can produce lesions of broadly shape No positive evidence exists for this contagion has not been proved, the lesion has been transmitted experimentally[5], and no bodies are present Nevertheless, virus infection the most likely cause FOURACRES and W suggest that the lesion may be related to the self-healing squamous carcinoma of FERGUSON and BEARE that it is related to the tumo keratoses of POTH[7]—though this seems less pro "Molluscum sebaceum" is not a very good for it has been used in other senses, and "sebaceous in any case probably misleading Kerat is a colourless term which has not been accepted Possibly "molluscum pseudoc tosum" best epitomises the main features

A good deal of work remains to be done, in a more extensive attempt to transmit the Confirmation of its occurrence in other co would be welcome (It was disappointing to find an account from New Zealand[8] referred only to seen in London) A few cases are known to have seen overseas—for example, in a Spaniard at Gi The lack of reports from other countries is pro due to unawareness of this entity, and there m much to be learnt from its geographical distrib If, as BEARE's figures suggest, as many as one

the lesions commonly reported as squamous cinoma of the skin are in fact mollusca, our statistics incidence and prognosis of skin cancer will need to drastically revised

The Banished Bacterium

AT meetings in Rome last month the International mmittee on Bacteriological Nomenclature rejected generic name *Bacterium* and the family name *cteriaceæ* Thus these names are no longer available systematists, but for a time at least *Bacterium* almost certainly continue to appear on report ms

Bacterium has had a long and checkered career It first used in 1828 by EHRENBERG for an organism, *terium triloculare* that cannot now be identified was once applied to spore forming as well as to sporing rods, LEHMANN and NEUMANN used it most gram negative rod shaped bacteria while in latest edition of *Bergey's Manual*[1] it was the eric name for the dump heap of unclassified rod ped bacteria both gram positive and gram ative In this country *Bacterium* was treated with her more respect, medical bacteriologists used it the lactose fermenting coliform organisms which chemists knowing little of bacteriological taxo ny and nomenclature called by the generic names d in *Bergey's Manual—Escherichia* and *Aerobacter* ne, including TOPLEY and WILSON[2] used *Bacterium* gram negative rods that were rather like coliforms , because of significant differences had to be luded from that group—for example *Bacterium tralum* and *Bacterium alcaligenes*

The problems facing the systematist—and these l eventually affect all bacteriologists and even tarians and clinicians—concern the renaming of ny well known species, including *Bacterium coli* l *Bacterium aerogenes* By the rules of bacterial nenclature the oldest name has priority but a mber of requirements have to be satisfied and it is the interpretation of these lesser considerations t doubt and debate may centre Classification st precede naming and the systematists robbed a convenient label for bacteria of uncertain taxo mic position must now do some heart-searching and ide into what genera existing or new these anisms best fit *Bacterium aerogenes* an organism und in water soil fæces and urine exemplifies systematist's difficulties Culturally it closely embles Friedländer's bacillus the cause of severe d often fatal pneumonia and it is also related ologically to Friedländer's bacillus. Some bacterio gists say they cannot distinguish the two, others parate them by origin (above or below the umbili s), a few attempt to distinguish them by differences for example the sliminess of colonies or the ability ferment certain sugars produce gas in fermentation produce the enzyme urease Even those who recog these organisms as separate species generally mit that they fall into the same genus The next oblem is their relation to other coliforms should *cterium coli* be grouped within the same genus? is question is important because on the answer depends the new generic name of *Bacterium coli* Friedländer's bacillus and *Bacterium aerogenes* resemble *Bacterium coli* in being gram negative rod shaped bacteria that ferment lactose but they differ from *Bacterium coli* in such characters as motility encapsulation, urease-production and the end products of glucose fermentation If these differences were always clear cut it would be easy to define two genera but there are so many intergrading forms that generic differentiation is difficult In general British bacteriologists have grouped these species together in the genus *Bacterium* whereas workers in other countries have split them among two or three genera Serologists and biochemists can each separate these coliforms into two large groups and the groups so formed by these workers of different outlook are surprisingly similar A grouping arrived at by two distinct approaches has more to commend it than one achieved from a single angle, and it is likely that, for a time at least this division into two groups will prevail

The problems of nomenclature should be considered in relation to the taxonomic schemes already mentioned For the single group used by British bacteriologists in the past the correct generic name appears to be *Klebsiella*, which has priority over later names such as *Aerobacter Calymmatobacterium* and *Encapsulatus* and by this plan we get the unusual combination *Klebsiella coli* Those who would separate the coli group from the aerogenes Friedländer group will use *Escherichia* and *Klebsiella* as generic names, while any who think that separate genera are needed for *Bacterium aerogenes* and Friedländer's bacillus will have three genera—*Escherichia Aerobacter* and *Klebsiella* How will other coliform bacteria fit into this new naming system? The intermediate types of the water bacteriologists will be known as *Escherichia freundii* and many late lactose-fermenting or non lactose fermenting paracolons (the Ballerup Bethesda and Alkalescens dispar groups) will fall in the genus *Escherichia* Some paracolons are more closely related to *Klebsiella aerogenes* and will be placed in the same genus Other paracolons (such as the Arizona group) are so closely related to the salmonellas that they could conveniently be made a subgroup or species of the genus *Salmonella*

Family names of bacteria are not often used, but one *Enterobacteriaceæ* has become popular as a convenient name for the coliform group of bacteria Plant pathologists object to it because the bacteria pathogenic to plants and related to the coliforms have not been found in the intestinal canal of animals. As a family name it does not accord with the rules and recommendations of the bacteriological code, which says that the stem of a family name should be that of a contained genus—there is no genus *Enterobacterium* By the rules the family name should be *Klebsiaceæ* or possibly *Escherichiaceæ* so perhaps it would be best to accept *Enterobacteriaceæ* as an exception to the rules

The newer names and combinations will seem strange to readers in this country but however much we may regret the passing of the familiar name *Bacterium coli* the use of the generic name *Bacterium* had, in other combinations become an anachronism Surely it is better to make a readjustment now than to continue to use *Bacterium* and be out of step with the rest of the world

Annotations

W H O. CONFERENCE ON MEDICAL STATISTICS

APPROPRIATELY enough, Somerset House, where Dr William Farr pioneered the use of vital records, is the venue of this week's W H O international conference on medical statistics No attempt is being made to cover the whole field of medical statistics, the conference is specifically concerned with the activities of the national committees on vital and health statistics established in many countries in recent years The idea of such national committees was first broached at the Paris conference on the 1948 Revision of the International List of Diseases and Causes of Death The aim was twofold—to delegate the intensive study of particular problems of general interest to different individual nations and, by regularly exchanging the special experience of each nation, to raise the standards of vital statistical work in all Stimulated by a recommendation from a later meeting of the World Health Organisation, such national committees were established in 29 different countries, and in 11 some analogous agency of the national health service is carrying out the same function In the United Kingdom, for example, the Registrar General's advisory committee has this responsibility A special unit of the W H O organisation in Geneva coördinates the work of the national committees, whose present interests centre round three main subjects

As we have pointed out before, difficulties in recording the cause of death arise particularly at the extremes of the age scale Special studies of fœtal deaths in relation to the stage of pregnancy, to multiple births, and to birth weight have, therefore, a first claim on national resources of vital statistical research The increasing awareness of the limitations of cancer therapy has given fresh impetus to a search for general factors in cancer ætiology, such as smoke pollution and industrial agents, which may be controlled by appropriate public action But no study of the epidemiology of cancer can be complete without accurate classification of neoplastic disease by site and stage and precise knowledge of the distribution of cancer mortality in relation to time, place, and domestic or occupational environment Sickness which needs hospital care is a heavy national burden For the intelligent administration of a national health service, we must know more about the load, measured in terms of inpatient and outpatient services, imposed by different diseases Where all cases of serious disease, such as the major psychoses, are treated in hospital, the analysis of hospital admission rates among different groups within a community may give epidemiological clues about the causation of mental disorders In other less incapacitating illnesses, grafting hospital data on to the results of special surveys of sickness treated at home may give sound indications of the prevalence of a particular disease and its relation to the several characteristics of the population—demographic, occupational, or domestic—described by the national census

A national committee need not itself undertake the particular study allocated to the country by W H O It serves rather as a catalyst, bringing the needs and interests of the profession to the notice of government statisticians, stimulating fresh work in vital statistics, and encouraging the training of statisticians and doctors in the collation of data from many sources and the interpretation of results Whatever its stage of technical development, these broad needs must be met in any country Whether the formal linking of national committee and international conference is the best way to achieve this remains to be seen, but the present meeting should help to clear the air The presence of Sir Russell Brain, the president of the Royal College of
as honorary president of the conference and head
delegation, supports our belief that modern
cannot afford to ignore the fruits of vital
research It would be idle to expect too much
single conference, the complexities of m
statistical relations cannot be readily solved in
lessons, but the clash of ideas will certainly p
useful fire

COMPRESSION AND BONY UNION

REMODELLING of bone is a dual process of
and osteogenesis, and if the surgeon could dis
actual stimulus to the osteoblast the solution to
problems would be in his hands In his new mono
Charnley reasons that this stimulus is compression
that it is effective only when two cancellous
surfaces are held against each other He be
with compression of cortical bone surfaces this
is ineffective, and he points out that in fractures
is always some death of bone cells in the cortical
adjacent to the fracture site Hitherto the only
mental evidence suggesting that pressure between
surfaces can promote osteogenesis comes from the
of Eggers,[2] done with a bone flap in the skull of
but, as Charnley points out, the forces applied
minute, and there were other factors which might
probably did) affect the rate of union Ch
criticism seems valid, and many will agree with
questioning the value of using slotted plates in
—a method designed to allow the bones to shorten
allowing the muscle tone to maintain pressure
the bone ends as they soften and are absorbed
normal early stages of fracture repair There is
some evidence that pressure between bone ends
harmful,[3] and the enthusiasm for early weight
after fractures is now declining Indeed Watson
condemns this practice He has also expressed
reasons for believing that compression is not
important factor in stimulating union, and C
in the best tradition of the old time pam
(but writing with greater courtesy), devotes a
to disposing of this argument His thesis is based
the work he has done on compression an
particularly in the knee-joint This method was orig
by Key[5] but has been popularised only as the
of Charnley's work It consists in producing two
surfaces by sawing off the joint surfaces of the
end of the femur and upper end of the tibia, trans
the bones with Steinmann's pins, and clamping the
pins together at their ends by means of special
clamps The pressure so generated more or less
the surfaces together, but an external splint from
to ankle is also used This method can also be ad
to other joints Fusion takes place very speedily,
whatever doubts may be felt about the explanation
would deny that the results are much better than
any other method In an uncomplicated case the p
is walking without support, and with bony union be
tibia and femur, eight weeks after operation, six m
(and often far longer) was a more usual period in
past By means of a special trephine, biopsy
mens have been obtained four weeks after op
at which time the pins are removed, a simple p
cylinder is applied, and ordinary walking is allo
and illustrations of some truly superb prepar

1 Compression Arthrodesis, including Central Dislocation
Principle in Hip Surgery By J CHARNLEY Edin
Livingstone 1953 Pp 264 42s

2 Eggers G W Steindler T O Pomerat, C M *J Bone Jt*
1949 **31A**, 693

3 Friedenberg Z B French G *Surg Gynec. Obstet* 1952 94

4 Watson Jones, R. Fractures and Joint Injuries Edin
1952 vol 1 p 223

5 Key J A *Sth med J* 1932, **25** 909

Prof S L Baker leave no doubt that true union has taken place at that time Baker arks that 'the union of the arthrodesis surfaces nese specimens shows the features of rapid healing ompletely immobilised fracture like that occasionally in an undisturbed impacted fracture, for example a s fracture '

he difficulty is, of course to find proof that it is the pressure rather than maintained intimacy of act alone that has brought about this eminently able result Charnley has designed an experiment, in but a single instance, in which by shaping one bone end into a blunt wedge different areas are ected to different pressures the difference in degree nion in these areas followed his prediction that the ter the pressure the better would be the osteogenesis nother case intimacy of contact was maintained by ling the bone ends together after compression had applied and then immediately removing the nmann pins and therewith of course the spring ment of the compression the usual *dramatically* d bony union failed to result and Charnley suggests this is evidence that intimacy of contact alone is enough It is possible to estimate roughly the sure used from the curvature created in the pins n the clamps are applied, and slow union was found tly in cases where for one reason or another pressure been inadequate

he evidence, so far as it goes, is good but not entirely ifying As Charnley *points out, biopsy material is* cult to come by and indeed the crucial experiment re some form of a pressure gradient is present at surfaces in contact has been done in a single case Charnley of course appreciates that this leaves work open to criticism But whatever one may think he merits of the evidence there is no doubt about excellence of the results With characteristic nuity Charnley has evolved methods by which the ciple can be applied to most joints which need fusion, in the process has evolved the idea of central dis tion as an important, if not vital, principle in surgery

PSYCHE AND SURGERY

HYSICIANS and surgeons in this country were unwilling slow to accept the view that partial gastrectomy is ified in the treatment of selected patients with peptic r; and after adopting resection in preference to tro-enterostomy they have justifiably remained ical of the end results as is shown by many careful ies of the post gastrectomy syndrome and the many ifications of the operation which have been designed educe the incidence of unpleasant sequelæ Even the t open minded, however will be surprised if not ken by the conclusions reached by Browning and seworth[1] after studying sixty patients treated for denal ulcer half by medical measures and half by tial gastrectomy Having followed up these patients at least a year after treatment, they found that the ically treated group revealed a significant decrease ulcer symptoms but that this was offset by a signifi t parallel increase in other psychosomatic and choneurotic symptoms. The medically treated group e not relieved of their ulcer symptoms but did not w the same tendency to develop other complaints over all incapacity was not reduced in either group other words duodenal ulcer is a psychosomatic disease if *effectively treated by surgery* without resolution the associated psychopathogenic conflicts' is likely heir view to be replaced by other no less incapacitating ptoms. Moreover this alarmingly defeatist conclusion is not relieved by any suggestion that the psychiatrist can deal any more successfully with the situation

If this conclusion is not to be accepted it must be refuted with evidence and argument Contrary evidence is not easily adduced because of the absence of similar studies in this country but it must be very unlikely that such seriously incapacitating conditions have been completely overlooked in the many careful reviews carried out here to refer to only one of these Muir[2] a physician reviewing surgically treated patients found that over 90% had some form of post-gastrectomy disturbance (including psychoneurotic symptoms) but concluded that In the great majority of these patients the operation was entirely successful all were agreed that their health was immeasurably improved' For argument perhaps the most obvious and serious criticism of the study by Browning and Houseworth is that their sixty patients were evidently a selected group They admit that the thirty medically treated cases of their control group ' were selected, being patients in whom complete *remission of ulcer symptoms did not occur* *It is difficult* to escape the suspicion that the surgically treated group were also patients who continued to attend hospital because they were not satisfied, if for no other reason than that no less than thirteen of the thirty still had ulcer symptoms For this and other reasons we may reject the conclusions but are reminded that a follow up of patients treated surgically for duodenal ulcer should include a search for other psychosomatic disorders of a conversion type

RECOVERY IN THE LOWER MOTOR NEURONE

WHEN the lower motor neurone is incapacitated, whether by trauma or by infection such as poliomyelitis it is important to find out how rapidly it is recovering and how much recovery may be expected Observation of voluntary contraction of the muscles supplied will give some information, but with a clinically complete lesion this may come too late to be of much value. In *a mixed motor and sensory nerve the course of sensory* recovery from peripheral trauma can sometimes be followed accurately by eliciting Tinel's sign but motor and sensory improvement do not always run pari passu In experienced hands the response of muscle to faradic and galvanic stimulation has proved a valuable source of additional information, and is still widely used It was early noted however, that faradic response was occasionally negative even when voluntary contraction proved that some re-innervation had taken place; and occasionally faradic response could be obtained in a muscle known to be denervated The search for more accurate methods of electro-diagnosis has therefore been pursued and Wynn Parry[3] discusses two such methods—serial strength duration curves, and electromyography

The curve obtained in normal muscle by plotting the voltage required to produce minimal contraction against the duration of the stimulus in milliseconds is characteristic For durations of from 300 to 0 3 milliseconds, the voltage is constant; for durations of from 0 3 to 0·01 milliseconds, it *rises* In denervated muscle also the general shape of the curve is typical. The voltage slowly *rises for* durations of from 300 to 10 milliseconds and for shorter durations than this the curve rises steeply With re innervation the denervated curve shows a kink in its previously smooth outline Further kinks may occur as recovery proceeds and these may combine and widen to give a long plateau until *the curve gradually assumes the normal* pattern Wynn Parry regards these kinks as a reliable and early indication of recovery He has never observed them in cases which did not later show some clinical recovery

rowning J S Houseworth J H *Psychosom. Med* 1953 15 328

[2] Muir A. *Brit. J Surg* 1949–50 37 165

[3] Wynn Parry C B *Brain*, 1953 76 229

and they precede any signs of this by an average of six weeks Moreover in some cases of nerve injury they appeared, but after a period of development towards the normal showed no further progress, thus suggesting some interference with recovery, and in such cases subsequent operation revealed a neuroma

Serial electromyography also proved of value in prognosis Fibrillation potentials might be observed throughout recovery, and sometimes persisted in small amounts even after full clinical recovery and were therefore of little prognostic value, but discrete low-amplitude potentials of short duration were seen on an average 8 weeks before any clinical contraction These discrete potentials were present even when clinical recovery was finally poor, but where final recovery was good they were followed in a few weeks by polyphasic potentials of longer duration So here also the milestones of good recovery seemed to be clearly indicated

These two methods are to some extent complementary The electromyograph will give more detailed information about that small sample of muscle accessible to the electrode, and if this is luckily placed it may give the earliest indication of recovery The strength-duration curve will give a more coarse assessment of a larger sample it will be less likely to miss the evidence of recovery, though it may record it rather later Both represent an undoubted advance on older methods For accurate interpretation, however, they require technical skill, and, especially in the case of the electromyogram, considerable experience

HÆMANGIOMAS

Angiomas of the skin disfigure but are seldom dangerous It follows that their treatment, undertaken for cosmetic reasons, should be harmless, but this is not always so Among the potentially hazardous treatments which have been recommended are various forms of radiotherapy and injections with sclerosing fluids, including boiling water Cases of aplasia of the breast or of stunted growth of a limb are seen from time to time to remind us that such risks are still taken In some centres, notably on the Continent, frank incredulity is expressed when the visitor remarks that many angiomas regress spontaneously[1–3], and here all angiomas in children are treated, so there is no opportunity to see what happens if they are left alone

The "strawberry" type of lesion is the one most likely to disappear spontaneously It may often be left to do so in areas not subject to friction or to the observation of over-anxious relatives Ulceration does not affect the good prognosis and may in fact accelerate fibrosis Very rapid growth is an indication for treatment, particularly on the face, where a bulky tumour can distort the growth of nearby structures In most cases treatment with carbon-dioxide snow, used with patience and discretion, is quite sufficient In others more complicated methods may be needed, and here the surgeon, the radiotherapist, and the dermatologist should be aware of what each can achieve

The "portwine stain," on the other hand, shows very little spontaneous improvement, except in the mildest examples Sometimes a gratifying amount of blanching may be obtained with Grenz rays without the risk of late radiation sequelæ, but this treatment is not widely available β radiation, in the form of thorium-X paint, has also been used There is a growing awareness that penetrating β-radiation and γ-radiation may occur in this treatment, and the investigations of medical physicists must be carried further before this method can be considered as harmless as was formerly supposed In women the lesions can be successfully concealed with opaque cosmetics for this purpose, but in men the effect may embarrassment if more than small areas are Conway[4] has described the camouflage of flammeus by tattooing pigments into the skin a technique which has been used in the restoration vermilion border of the lip and in the " of facial grafts The treatment is relatively and an area of from 4 to 6 sq in can be treated sitting In seven years 310 patients applied for ment, and of these 85% were selected as likely to from it 159 obtained a result satisfactory to surgeon and themselves—i e, about half those who for an opinion If the lesion is too superficial, pigment is rapidly swept away in the blood, presumably patients with thick, tumid lesions of for example, do not obtain conspicuous benefit W its limitations, however, this seems to be a treatment worthy of further trial

WEANING

From the moment we are pushed willynilly from womb we start to live dangerously, indeed, the passage to the outer world is our first great After that come breathing hazards, feeding and hazards of elimination, all before we have le mothers' arms One very serious risk, which Le Gros Clark[5] thinks we are inclined to und comes at the time of weaning Animals, as they accompanied by their young, through their edible world, manage the tricky business much the young need only watch and copy the pare order to fill their bellies with appropriate and victuals How different is the lot of the human whose internal arrangements seem much worse to deal with contaminating bacteria than those lamb, a calf, or a puppy, and who is conscio anxiously fed by a mother whose ideas derive from social customs and food resources of her communit

In countries where the milk-supply is clean and and mothers are reasonably well educated, the course, are much reduced for clean cow's milk convenient and digestible transitional food for a old enough to be weaned But milch herds are a acquisition in the history of man, and even today of the people in the world have little or no milk mother's milk Suckling and weaning among such peoples has assumed, Mr Le Gros Clark sa magic or ritual significance Only in a few tribes customary to stop suckling the child before the en his first year he is more usually breast fed for an up to four years If maternal milk was his only n ment during that time, he would suffer badly malnutrition, but since other foods are given and even stuffed into him, almost from the start of he commonly suffers from indigestion as well In tribes the mother denies the child the breast fo first few days, or even the first fortnight of life, gives him other provender such as chewed banana This practice at least ensures that only the survive In Rome, Ethiopia, and India butter m the first food given to the child, while the Ba start him off on millet gruel Among the Chag East Africa breast-milk is supplemented, from the s day onwards, with a pap made of milk or butter with unripe bananas and soda (used instead of and from his third month the baby gets a tas everything going, including meat Being used to mixed diet, he hardly notices weaning, except disciplinary action—which, in fact, is the usua made of it

[4] Conway, H *J Amer med Ass* 1953, 152 666
[5] *Nutrition* Summer 1953 Published by Newman Book 68, Welbeck Street, London, W 1

r Le Gros Clark has many such examples to quote, h well illustrate his point that the human mother e other mammals has no instinctive" way of ing her young; yet her young are more utterly ndent on her than those of any other mammal a the newborn ape nuzzles for the nipple, and res its own safety, when its gymnastic parent moves linging fast to her with hands and feet The depen e of the human infant must he thinks have been atter of gradual adaptations the clinging reflex d not have been safely lost until maternal care had hed a very advanced stage The infant, as we all v, believes in chewing anything he can put into mouth and how he fares on what he chews pre ably depends on the nutrients he can extract from it Le Gros Clark suggests that by the time human its had become as helpless as they are today their lies had become meat-eaters and raw meat can, ays, be chewed with some profit: indeed, Chinese ners still give their children premasticated scraps of The trouble arose when a tribe settled down vated grains, and began to live on a predominantly hy diet. For the staple foods, though just sufficient dults, might then be too poor in proteins, calcium other nutrients to protect the weaned child from us deficiency disease When a child has to learn to on a starchy diet of this kind, prolonged breast ng may give him just the diminishing amount of ein needed to tip the scale of amino-acid sufficiency e question is whether we can raise weaning diets ll parts of the world to an adequate level Mr ros Clark thinks that this might be done by supplying milk, dried skim milk or some milk substitute to les living at such a low economic level that the ren are inevitably malnourished We may also lder some of the cereal and soya mixtures used ssfully in the study[4] recently reported made by Medical Research Council in Germany between 1947 and early 1949 In these mixtures, all the ssary proteins were present, and children aged 11 years did well on them. Even children under a old still throve when about half the milk in their was replaced by such mixtures

MECHANISM OF COLD VASODILATATION

HEN a finger is immersed in ice-cold water intense constriction results. This lasts for about six minutes, is followed by vasodilatation Vasodilatation occurs nervated and in anæsthetised fingers and is therefore ted, at least partly by a humoral mechanism Duff his collaborators[7] have attempted to explore the played by histamine and acetylcholine in this reac

Their technique is difficult and ingenious: a r is inserted in the ice-cold water in a calorimeter the rate of heat loss from the finger gives an indica of the circulation through it. These investigators d that the introduction into the finger of histamine acetylcholine did not influence the vasodilatation ortunately however this provides no definite evidence r for or against these substances being concerned he natural response since it is impossible to be sure the drugs actually reach the blood vessels in uate concentration modification of the vasodilata response can only be observed after preliminary cold constriction so it is impossible to tell whether a introduced into a remote artery has reached the being tested Even when the drug is introduced ugh the skin by electrophoresis its eventual distribu may depend largely on the local circulation and be much reduced when the vessels are constricted cold.

Another experiment, employing a slightly different approach proved more fruitful Atropine was introduced by electrophoresis into one finger, where it was shown to block the vasodilator response of acetylcholine at 29°C When this atropinised finger was inserted in ice cold water its vascular responses differed in no way from those of a control finger This neat experiment suggests that acetylcholine is unlikely to play a part in the vasodilatation induced by cold. In a parallel experiment designed to determine indirectly the part played by histamine it was not found possible as a necessary preliminary to demonstrate blocking of histamine responses at 20°C after electrophoresis of various antihistamines This failure rendered experiments in the cold of no value.

A different finding by this same group of workers originates from the clinical observation that in patients with a high titre of cold agglutinins in their serum the digits may become numb and cyanosed when exposed to cold Careful experiment has shown[8] that this effect is due not to vasospasm but to blockage of small vessels by agglutinated red cells—a change which happily is reversible

VARICELLA ENCEPHALITIS

ENCEPHALITIS is a rarer complication of chickenpox than of measles.[9] Of 6774 cases of chickenpox admitted to the Willard Parker Hospital in the years 1941–50, 18 (0 26%) were complicated by encephalitis[10]—an unusually high figure Few experienced observers in this country can claim to have seen more than one or two cases. Most of the clinical records reported since Underwood's[11] comprehensive review of 120 cases describe single cases It is most valuable therefore to have a new study by Appelbaum and his colleagues[10] of no less than 59 cases 32 of which were observed at the Willard Parker Hospital during the years 1938–52 and 27 in the New York City Health Department during the years 1931–51

The pathology of varicella encephalitis as far as it is known, is broadly similar to that of other postinfectious encephalitides in being predominantly of demyelinating type In each of the 6 reported cases confirmed by histological findings there was damage to the myelin varying from perivascular loss to severe softening of the white matter Inflammatory perivascular infiltration with round cells or fat-containing phagocytes was also present in every case. In addition, degenerative changes in the neurons were observed in 3 of these 6 cases The one necropsy in Appelbaum's series, however showed no loss of myelin, but merely perivascular œdema and slight cuffing This may have been related to the fact that the patient died very soon after the onset of symptoms The most common age for this complication (as in measles) is between 5 and 7 years and of Appelbaum's cases 65% were not more than 11 years of age but the ages ranged from 8 months to 71 years The onset was most commonly between the 3rd and the 8th posteruptive days, although in 1 case it appeared coincidently with the rash and in another case 21 days thereafter The onset was most often dramatic, with headache vomiting fever, and a change in the sensorium sometimes with convulsions and paralysis as well Of the 59 patients in the series, onset was more gradual in 20 with irritability drowsiness and ataxia. The clinical course was very varied almost every sign indicative of central nervous system involvement being encountered; the commonest signs and symptoms in the 59 cases were neck stiffness (29) drowsiness (27) headache vomiting fever (33, 34 39) ataxia (16) convulsions (13) apathy (15) and stupor (11)

[11] Underwood E. A *Brit. J Child Dis.* 1935 32 83 177 241

The most usual findings in the cerebrospinal fluid were moderate increase in the white cells (only 10 cases showing more than 100 cells per c mm) and slightly increased protein The outstanding differential point in the diagnosis was the concurrence of clinical manifestations of encephalitis with a varicella rash at any stage The prognosis was relatively favourable, the fatality-rate was only 5%, and 80% of the patients were discharged from hospital without any neurological or other detectable abnormalities A follow-up of 33 cases for periods varying from 6 months to 13 years revealed neurological sequelæ in 10, and in 3 of these they first appeared 6 months to 3 years after discharge from hospital On the patient's discharge the prognosis must be somewhat guarded, for occasionally the neurological pattern later changes significantly The treatment in this series was entirely symptomatic, but in view of the work of Kabat et al[12] and of Moyer et al[13] on the suppression of experimental demyelinating encephalomyelitis with cortisone or corticotrophin (A C T H), the administration of these hormones in the early phase of varicella encephalomyelitis should certainly be considered

UTERINE CARCINOMA

Mass statistics play an important part in assessing progress in treatment, and those who have collected data will appreciate the difficulties that Dr J Heyman and his editorial committee have overcome in presenting the results in 83,291 cases of uterine carcinoma from 69 institutions in 15 different countries[14] The improvement in results is shown by the fact that the 5-year over-all apparent recovery rate has increased from 26 3% in a report issued in 1938 to 34·1% in the latest report, and for the latest 5 years covered by this report the rate is 38% Altogether 78,943 cases of carcinoma of the cervix are included, of these, 73,612 were treated 17% were in stage I and had a 5 year recovery rate of 59 9%, 36 2% were in stage II with a recovery rate of 41 1%, 35 9% were in stage III with a recovery-rate of 23 2%, and 10 9% were in stage IV with a recovery rate of 6 7% Cases of carcinoma in situ (stage 0) are not included

Against this background it is interesting to study the excellent results described by Meigs[15] in 100 cases of carcinoma of the cervix personally treated by radical hysterectomy and lymphadenectomy Meigs looks on this series as a pilot experiment, and he deliberately selected stage I and stage-II cases in "good risk, fairly young and not too fat patients" There was no operative mortality, and after 5 years 75% were alive and showed no evidence of carcinoma It is important that of the 100 patients 46 had some preoperative radiation Meigs believes that X ray and radium therapy is still the proper treatment for this disease He calls for closer cooperation between radiologist and gynæcologist and for greater individualisation of radiation therapy, and he deplores routine applications of radiation by the gynæcologically or surgically unskilled radiologist In this country cancer cases are now sometimes referred direct by the practitioner to the radiotherapist and are treated without consultation with the appropriate specialist Such an arrangement will not always result in the patient receiving the most suitable treatment; and the only solution is closer collaboration between radiotherapist and surgeon or gynæcologist

The preliminary results of another experiment in therapy have been set out by Gorton,[16] who since 1948 has treated at Lund 162 cases of cervical carcinoma by extraperitoneal lymphadenectomy after full radiation by the Stockholm method This plan of therapy new, but the material is very carefully presented. 181 patients operated on (including the 162 who went extraperitoneal lymphadenectomy) lymph metastases were found in only 15 5%. This is lower proportion than has usually been found for st and II Gorton claims this as evidence that often destroys carcinoma in regional lymph node concludes that the 5 year recovery rate for cases by irradiation only is about 40%, that surgery has been proved superior to radiotherapy, that an ade dose cannot be delivered to the lymph nodes alo pelvic wall, that the nodes are a common site of rence, and that involvement of the nodes cannot be recognised before treatment It seems a pity that has given such a detailed account when, in more half the cases, only 2 years have elapsed since He rightly claims that with other forms of recurrence rate falls rapidly after 2 years, but it be presumed that this will be so for the treatment chosen

Way and his co workers[17] are treating stage carcinoma of the cervix by radiation followed by ectomy (either radical or simple, depending on rad response) and lymphadenectomy Of 213 cases, showed lymph-node metastases 6–8 weeks after Lymphatic involvement was significantly comm stage II than in stage I, with anaplastic than with entiating tumours, and in patients with tumour in the cervix than in patients whose tumours had after radiation

The difference between Gorton's 15 5% node ment and Way's 45%—both in cases previously —cannot be explained alone by the fact that operated 4 months after radiation and Way 6–8 Considering this difference in the light of Meigs's tion that, among 100 cases, 17 of the 23 with nodes died within 5 years, compared with 8 of with negative nodes, it is clear that very large need to be carefully studied before two treatment can be fairly compared

SCIENTIFIC BASIS OF MEDICINE

In 1950 the British Postgraduate Medical F arranged the first of an annual series of lectures mainly to indicate to young research workers specialists in training the scientific basis of their of other subjects That year the introductory was given by Sir Henry Dale, O M, F.R S, and week, on Oct 8, Sir Henry introduced the fourth Tracing the development of medicine over the past hundred years, he remarked that even at the turn last century there was a progressively dominant tion in medicine, and to a lesser extent in surgery, clinical work was an empirical art or craft—"a priesthood"—and certainly not a science. were not only unscientific but specifically antisc Lacking firm evidence from controlled experimen clinician could take his choice of remedies, and th value of citrus fruit juices in the treatment of and of cod liver oil in the treatment of rickets had repeatedly forgotten and rediscovered Now, it was recognised that the study of the patient follow the scientific method, and firm partne been established between workers in the sciences and clinical investigators In this part chemists were playing a leading part, and Sir cited as an example news that he had lately America of the isolation, identification, and even lation of the oxytocic hormone of the posterior pi a development that he had never pictured when recognised this hormone forty eight years ago

Points of View

✓

THE PLACEBO
ITS USE AND ABUSE

A Barham Carter
M D Camb., M.R C.P D.P.M.
PHYSICIAN ASHFORD HOSPITAL, MIDDLESEX

ACCORDING to the *Shorter Oxford Dictionary* a placebo a medicine given more to please than to benefit patient." To me this is a contradiction in terms hing that pleases me does me good Yet it probably *ribes well enough what we mean by the word.* To a placebo may be the correct treatment for a patient needs a material sign that we are trying to help and who from a scientific point of view at any is past our help Like any other treatment, it be misused and the placebo has fallen into the ter disrepute because it can so easily become the ustay of quackery But its intelligent use can be eat help to patients and doctors alike

Uses

For a patient with malignant or degenerative se where no adequate scientific treatment is known diseases as progressive motor neurone disease minated sclerosis, and carcinomatosis often occur *entally active people and terrible depression* and ppiness may be caused by a plain statement to the nt that 'nothing can be done.' I therefore defend use of vitamin E liver or vitamin B_{12} injections and s in these conditions

For psychoneurotic patients who need a material to establish confidence so that they will benefit the real helpful psychotherapy that follows So a patient believes that his doctor has failed ause he only talked to me and words can't help trouble. For these patients I think valerian is est placebo and probably better without the usual ide

For patients in hospital for prolonged investigations. ve given up using placebos myself in this way use I find that patients usually accept an explanation they can understand

Abuses

Giving a placebo instead of taking an adequate ry and making an adequate physical examination is the major crime and the deadliest of medical and has got the poor placebo into disrepute It s most mistakes in diagnosis and treatment—e g., onic for the primary depressive state bromide for hyrotoxic patient, white mixture for the carcinoma mach vitamins for pulmonary tuberculosis

Giving a placebo in the belief that it is a scientific nent This is probably the fault of the wholesale manufacturer as much as anyone I instance the f vitamin B in painful sciatic or other forms of tis the use of certain vegetable extracts in hyper n and the use of testosterone in psychoneurotic tence

Giving a placebo in the belief that no scientific ment exists, when in fact it does Primary depressive may be treated for years with tonics such as anine when the illness might be cut short by oconvulsion therapy

Giving an expensive preparation as a placebo is not uncommon and greatly encouraged by tising

Giving a placebo on demand We all have patients demand tonics cough mixtures something for the s or physiotherapy for minor ailments

6 Continuing to give a placebo for a long time I saw a patient not long ago who had had a urinary infection possibly venereal in origin and ten years later was still on methylene blue

Conclusions

The above list of uses and abuses suggests four general principles for prescribing placebos

The patient must have been properly examined, investigated and listened to
The drug prescribed should be cheap and non toxic
No really effective treatment should be available
The treatment should not be unduly prolonged.

We must beware of prescribing the placebo to please the doctor rather than the patient for a feeling that something has been done may blind us to any change in symptoms and may prevent that constant alertness so necessary to good doctoring Nevertheless there is a not inconsiderable place for the placebo in medicine and if intelligently used I will defend it to the last drop in the bottle

A BOTTLE OF MEDICINE FROM THE DOCTOR

R P C Handfield-Jones
B.M. Oxfd M.R C P D Obst
GENERAL PRACTITIONER, GLOUCESTERSHIRE

> Faith in the gods or in the saints cures one faith in little pills another, hypnotic suggestion a third faith in a plain common doctor a fourth (Osler 1901)

> the desire to take medicine is one feature which distinguishes man the animal from his fellow creatures It is really one of the most serious difficulties with which we have to contend (Osler 1894)

> Babes are not born with a desire to take a drug for every symptom—they acquire this desire Who teaches them? You and I do We educate our patients and their friends to believe that every or almost every symptom and disease can be benefited by a drug" (Cabot 1906)

IT has been said that the specialist observes his specimens in the zoo while the general practitioner pursues his quarry through the jungle (Barber 1951) One of the problems that beset the doctor who leaves the zoo for the jungle is the placebo accustomed to using drugs for a well defined pharmacological effect he is puzzled to find inert medicines given as a means of suggestion or because the patients expect them Having recently come to general practice I offer the following observations and reflections with humility in the hope that they may provoke others more able and experienced to throw light on what is now a major national problem My purpose is to consider why placebos are so widely used whether the patient is well served thereby, and what place placebos would have in an ideal practice where there was enough time to work without being hurried Are placebos part of the Art of Medicine, or are they unfortunate necessities?

A placebo is defined as an inert drug given to satisfy the patient. The word 'inert' is vague, and I have included those drugs which have no pharmacological action and those which are commonly given in inappropriate circumstances or inadequate doses mainly for their power of suggestion Among these I would include all tonics most of the vitamin and hormone preparations as currently used and a host of proprietary combinations of old favourites offered in fancy dress and with new names as great advances It could be maintained that many potent drugs such as barbiturates, amphetamine and anti histamine preparations are commonly used so uncritically as to fall into the placebo class.

The scope of the problem is best illustrated by the size of the nation's bill for drugs The estimated cost of drugs prescribed by general practitioners under the National Health Service for 1953–4 is £46$^1/_2$ million, and the number of prescriptions is likely to be over 200 million, that is an average of about 5 prescriptions per person at a cost of a little over £1 In 1952 proprietary drugs represented 26% of the total number of prescriptions and 44 5% of their cost (Macleod 1953)

If the figures collected from 17,301 prescription forms (Dunlop 1952) are a fair sample of the whole, a third of prescriptions in general practice are for tonics, stomachics, and sedative and hypnotics combined, whereas penicillin, sulphonamides, bronchial dilators, iron preparations, cardiac drugs, hormones, liver extracts, and strong analgesics together account for only a fifth

Arguments in Favour of the Placebo

> "Indeed, with the world as it now is nothing could be more calamitous than to rob the people of this kind of sickness, for as things are there appears to be no escape from perplexity and uncongeniality for thousands amongst us other than through the narrow neck of the bottle of medicine To a large extent one of the major social functions of medicine has thus unfortunately become the provision of comfort for the inefficient and of support for those who, because of their own inadequacies, cannot cope with circumstance" (CREW 1953)

Some of the reasons for giving placebos are that the patient expects a bottle of medicine, he has faith in it, and it makes him feel better, the doctor's task is to make the sick whole and if placebos do that they are justified The medicine bottle carries with it a magic charm of suggestion and comfort, and is a token that the doctor has taken upon himself the patient's problems It is harmless, an innocent indulgence which provides the same sort of solace as does the beer or spirit bottle to the patient's more robust friends If the doctor refused to give a placebo the patient would consider that he did not care, was mean, or had given up interest and hope, the patient would go to another doctor who had no scruples about it Many of the general practitioner's patients are unhappy, discontented, and unfulfilled, and comfort is so easily supplied to them in this way

To the busy doctor perhaps the most cogent reason is that it is quicker to give a placebo than to refuse it Those of the profession who feel inclined to criticise the general practitioner's methods should, in fairness, try to imagine how they would cope with an evening surgery at the end of a busy day, when the waiting-room was full and the queue extended down the front garden to the street This is not fanciful, it is the everyday experience of many of the profession and is described in the Collings report (Collings 1950) In such circumstances careful examination, considered diagnosis, and logical treatment or superficial psychotherapy are out of the question, and the only way to work through the queue is to provide each with what he came for, a bottle of medicine

I do not suggest that these conditions of practice are the rule or that they are inevitable, but they are common enough The placebo habit is often due to too much work and too little time, and the only solution lies in smaller lists and better organisation, which we must hope will come with group practice, the Danckwerts award, and ultimately, perhaps, the health centres

The Dangers of the Placebo

1 *The placebo is a form of deceit, initially of the patient, ultimately of the doctor*

We like to think that our patients bring us their symptoms and problems for our consideration, expecting thoughtful and honest advice With the increase in minor psychological illness—"the malaise of maladjustment" (Crew 1953)—and the declining influence of the Church the doctor's value to the community as an impartial and educated adviser has become as important priest's used to be The placebo is a form of deception and a betrayal of trust equivalent to of bottles of ditch-water as water of the River

The faith of patients in the doctor's limits, many are sufficiently critical to recognise which does them no good Perhaps it happens often than we like to think that a doctor gives because he thinks the patient expects it, and the drinks it (or secretly pours it down the drain) be does not want to hurt the doctor's feelings go on for years

> "Placebos have another bad result They confidence of the patient in the physician, because placebo is a lie, and in the long run the lie is found out give a placebo with one meaning, the patient with quite another. We mean him to suppose that the acts directly on his body, not through his mind by of expectant attention If the patient finds out are doing he laughs at it or is rightly angry with have seen both the laughter and the anger—at our Placebo giving is quackery" (CABOT 1906)

Ultimately the doctor deceives himself, loses objective view of therapy, trying out drugs which do some good, without ever being able to find out have It is essential for the doctor to preserve view of therapeutics if he is not to lose himself profusion of new remedies and become a prey drug firms and their new polypharmacy To the there is need for much more postgraduate from the College of General Practitioners, the hospitals, and universities, at present it is largely hands of the drug firms and their travellers

2 *Placebo giving prevents early diagnosis*

The effect of the placebo habit is that di neglected, a short cut is taken from symptoms ment, the underlying reason is lack of time. is that the young man with pulmonary given a tonic until he has a hæmoptysis, and the aged man with a carcinoma of the stomach has of alkali until the growth is self evident and inop Of carcinoma of the lung referred to the th less than a quarter are operable (Brock 1950). figure will be improved only when the general pract confronted with a middle-aged man with a recent onset has the time and facilities to chest and order a chest radiograph instead of bottle of cough mixture

The placebo is a relic of the days when there effective therapy The doctor's duty was to as patient that he was being cared for Now the holds the power of life and death in many dis temporising with bottles of medicine may rob the of his chance of cure

3 *Placebos produce neuroses*

> "But it is a fallacy to suppose that an inactive can do no harm. If prescribed in a perfunctory patient needing explanation and reassurance it may faith in his disease rather than in the remedy, and who gives a placebo in the wrong spirit may patient" (*British Medical Journal* 1952)

Many of the patients in the doctor's surgery because they have come into conflict with their ment or with themselves Although some are tionally and incurably neurotic, many have come for reassurance which would readily set the right road to recovery

A married woman of 46 complained of frequent lower abdominal pain and mild diarrhœa During the there was tenderness and voluntary guarding in fossæ Nothing abnormal was found on rectal exam and the temperature and pulse were normal, she theless, prostrated and kept to her bed In the had a cæsarean section and a perforated appendix removed, it was feared that adhesions might be pres rning I was sent for urgently because she had collapsed with scream of pain and been found prostrate though not onscious. I was able to satisfy myself that there was no anic disease in the abdomen and with a little encourage nt she told me of her worries over her husband, who had rnicious anaemia; the latest haemoglobin estimation was 'o, which to her meant that he was deteriorating rapidly feared that he would have to give up his job teaching in a versity department and then their only daughter would e to leave a fashionable school. She felt caught in a trap lecided which of her family should be sacrificed to the other t was easy to point out that there was no problem there all and that her husband's health was in fact very good accepted this with evident relief and was able to get up d do her work without pain although she was a chronic rier and would need helping through similar crises in the ire.

There is nothing at all unusual about this case and actitioners will be able to recall many similar but it is example of a patient to whom it would be disastrous give a placebo—to be on the safe side—since it would gest to her that the doctor had found something ong So the fear of organic disease is confirmed

Many of our patients behind their trivial and incon uential complaints hide unspeakable fears; fears of cer tuberculosis, blood pressure prolonged suffering okes and sudden death For them we can provide ef only by learning what they are afraid of If he is l that there is nothing wrong the patient decides that doctor does not understand his symptoms if he is en a bottle of medicine his worst suspicions are firmed

Placebos are inadequate therapy

bottle of inert medicine is a poor substitute for ctive symptomatic treatment such as analgesics for ritic pains or barbiturates to provide restful nights, for the careful regulation of the patient's activities , and habits which is necessary in chronic diseases so t he may adjust himself to his limitations and make the t of a crippled life

t may also stand in the way of specialist treatment in pital The increasing complexity of medicine places itional responsibility on the general practitioner since alone can make available to the patient the benefits of specialist departments His patient's welfare depends the doctor being in touch with the recent advances and wing what the hospitals have to offer This is a heavy onsibility and in no way devalues the general titioner's status to that of a sorting clerk. For many ients effective treatment can be provided only by a nber of people working together whether at home or hospital the family doctor has an important place ong them

o nervous patients investigation in hospital is often range and unnerving experience Repeated history ngs, examinations, radiography and venepunctures ncrease the patient's conviction that he is a sick man rring a patient from one department to another tributes to his demoralisation The general practi er can recognise this more clearly than the specialist it is his duty to some of his patients to keep them iome.

Placebos are a waste of time

lthough it may be quicker to give a bottle of medicine a to refuse it in the long run it makes more work n it saves for those who have had one bottle will e again for another and so the surgery will be crowded patients asking for just one more bottle, please

Is There a Place for the Placebo ?

ittle attention has been given to the many general tices where drugs are prescribed sparingly and with rimination Pinsent (1951 1952) in an analysis of l consultations in his practice found that 1458 were administrative The drugs he prescribed at the remaining 6606 consultations could be classified as follows

	%
A. Specific (antibiotics immunisation liver iron insulin, &c.)	10–15
B. Symptomatic treatment with drugs designed to alleviate symptoms as well as to affect the course of the disease	10
C Symptomatic treatment, more suggestive than pharmacological	20–25
D Placebo. Less than	10
E None	40–50

In prescribing these rare placebos Pinsent deliberately used the faith of many older patients that the doctor knows the remedy uniquely applicable to their cases He gave no placebos to patients under the age of 40 instead offering them advice and guidance on how they might help themselves. Medication was replaced by a conscious effort at instruction of the patient, and this change was well accepted by the patients though some whose confidence could not be retained were no doubt lost to the practice Pinsent holds that

> the mother with her first baby requires guidance the young man who fears tuberculosis needs the therapy of a complete examination followed by reassurance the old patient must be taught how to live up to but within, the limits of her failing powers This teaching can only come from the family doctor the general practitioner who is perhaps serving a more useful purpose when he advises than when he prescribes.

This inspiring example of honest therapy makes it clear that, although as a matter of *practical politics* general practice cannot be run without placebos, they need play but a small part in treatment and that time and the fear of losing patients are the chief reasons for *their widespread use*

Conclusion

There is a small place in practice for the placebo as a means of reinforcing a patient's confidence in his recovery when the diagnosis is known and there is no specific treatment Medicine should not become a habit

A patient who asks for a tonic often needs some specific treatment, such as iron for anaemia

Some patients are so unintelligent neurotic or *inadequate as to be incurable and life is made easier for* them by a placebo It has been said that the use of placebos is in inverse ratio to the combined intelligences of patient and doctor (Platt 1947)

It is usually best to humour an elderly patient who has been brought up on the bottle

The doctor who gives a placebo must be certain in his *own mind that it is completely inert, rather than entertain* a half hearted idea that it may do some good

Placebos should not be given if the diagnosis is in doubt particularly if there is any possibility of malignant disease.

Placebos should not be given to worried and distressed patients, who need help in readjusting themselves to their *environment or relief from unfounded fears*

It is a pleasure to thank many friends for advice especially Dr J E Jameson Dr G O Barber Dr A. M. Cooke Dr J A Fisher Dr Doris Odlum and Dr Pinsent and Miss P Browne for secretarial help

Medical Conferences

CARDIAC PHYSIOLOGY AND SURGERY

A SYMPOSIUM on Recent Advances in Cardiac Physiology and Surgery took place in Minneapolis on Sept 14–16 This was sponsored jointly by the University of Minnesota and the Minnesota Heart Association

Contractile Activity

W F H M **Mommaerts** (Cleveland) discussed contractile activity, admitting that much of the work had been done on striated muscle rather than on cardiac muscle It is presumed, however, that the contractile process is similar in both forms of muscle, though contraction is slower to follow stimulation in cardiac muscle Actin and myosin have been obtained from both Adenosine triphosphate is believed to be used up in cardiac contraction, for if the heart is brought to a sudden standstill by dropping it into liquid air this substance is found, but its concentration is greatly diminished in the beating heart Purkinje tissue has been found to contain a specific acetylcholine esterase which is instrumental in the conduction of stimuli

The account was continued by **Olle Snellman** (Uppsala) In heart muscle a complex of actin, nucleotropomyosin, and protein has been found and termed actotropomyosin It is thought to have phosphatase and deaminase properties and to react with cardiac glucosides

Blood Volume and Heart Volume

Torgny Sjöstrand (Stockholm) had found that capacity of the vascular system, blood volume, and end diastolic heart volume are related to each other The heart volume is related to a person's work capacity, and, at rest and during work, related to the stroke volume and also the total body blood volume The pulse frequency at rest appears to be related to the heart volume and the quantity of hæmoglobin in the body In cardiac failure the blood volume and the heart volume are increased and the cardiac output lowered

Otto H Gauer (Dayton) described the mechanism by which small increments of blood volume cause an increase in pulmonary and systemic venous pressure which stimulates stretch receptors and reflexly causes a water diuresis, restoring the blood volume to normal

Anatomy of Ventricles

R F **Rushmer** (Seattle) described the new anatomy of the cardiac ventricles The left ventricle approximates to a cylinder with a cone on top of it Ejection is mainly the result of reduction in diameter of the cylinder Such architecture is well suited for ejection of blood against a high resistance In contrast the right ventricle is bounded by the convex interventricular septum and a free wall which is concave This shape has a much greater surface area per unit volume than the left ventricle and is adapted to ejecting large volumes against low resistance When the right ventricle hypertrophies against pressure it comes more to resemble the left Observations of ventricular diameter, using intraventricular gauges in unanæsthetised dogs, have shown that neither ventricle empties completely, so that increased stroke volume may be achieved either by more complete ejection or by greater diastolic filling When the animal is startled, an increase in systolic and diastolic heart size is seen within the space of one beat, the manner in which this occurs is not known, but the effect is that tension can be maintained with a minimal shortening of the myocardial fibres Atrial systole does not result in a material volume increase of the ventricle

Oxygen Transport

R W **Stow** (Columbus) considered the systematic errors which may occur when the Fick principle is applied to oxygen transport The measurement of oxygen consumption may not be reliable, and if the rate of flow and the oxygen content of blood at the sampling sites vary in a cyclic manner certain discrepancies may occur The importance of these factors cannot yet be determined A **Cournand** (New York) reported that Dr **Gregg** (Washington) had found that the Fick method does agree with a direct method (Rotameter), but this may not be so when low concentrations of oxygen bed

Flow and Pressure in Arterial System

Discussing flow and pressure in the arterial WETTERER (Munich) considered two physical systems of the air chamber *Windkessel*, and those of the elastic the arteries He suggested that determination of di may be based on volume pressure relationships of parts of the arterial system or indirectly on of the pulse wave velocity As so measured, the disten of the arterial system appeared to be more closely body-weight than to age and sex

E **Wood** (Rochester, Minn) emphasised the desirabi determining the characteristics of any measuring and the impossibility of eliminating artefacts when through a cardiac catheter

Cardiac Output

C W **Sheppard** (Oak Ridge) considered the dye technique of estimation of cardiac output. Even in of a dye being simply injected into a straight tube which water is flowing steadily, the mixing curve differ what would be expected, in particular, the dye appea than the theoretical appearance time To take into the movements of dye within the fluid as it passes the web of the capillaries the statistical approach "random walk" is used Instead of time the fraction circulatory bed displaced is chosen as the variable, so that the curves come to depend on a ing constant" This theoretical approach can partia the form of the dye curve obtained

Stroke Volume and Pulse Contour

The relationship between stroke volume and pulse was discussed by J W **Remington** (Augusta) He f the net volume increase of the arterial bed during sy be equated with the time pressure area under the contour By this means the volume increase can be mined under 25% in man and within 15% in dogs area under the pulse contour is further corrected for th increase due to the pulse wave, the stroke volume determined to within ±15% of that found by appl the Fick method On occasions, however, the two volumes become markedly divergent It was also simple formula employing pulse pressure and (Erlanger and Hooker) gave a measure of cardiac sufficiently accurate for clinical purposes

Diagnosis of Congenital Heart-disease

L **Dexter** (Boston) dealt with methods of d congenital heart disease The cardiac catheter is useful in the diagnosis of a left to right shunt, though of the exact site of the shunt may be difficult. If the fails to give clear evidence of a shunt, it is unlikely shunt is of clinical significance Catheterisation demo a stenosis by showing a pressure drop over the const and the finding of equal pressures in the two ventricles a free communication between them The diagnosis patient with complicated congenital heart-disease be made on the findings at catheterisation alone but that all available data should be put together

H J C **Swan** (Rochester, Minn) dealt with the dye dilution curves in the diagnosis of congenital disease He demonstrated how the time-concen relationships of an indicator rapidly injected into the lation are affected by the vascular pathway traversed there is a right to left shunt the interval between the and the first arrival of the indicator at the sampling shortened, there is also a double-hump pattern due dye which has not traversed the shunt With a left shunt the appearance time is normal, but the slope declining curve is prolonged because of the recirc through the pulmonary circuit It is possible to estima approximate size of the shunt from these curves, injections into different cardiac chambers it is poss localise the shunt To take full advantage of the it is necessary that the observer should evaluate his at the time of catheterisation

E V **Newman** (Nashville) emphasised the diffi calibrating the concentration of the blue dye T 1824 a background of cyanosed blood The shape of centration curve obtained may depend on the rate at d is caused to flow through the sampling tubes. When oncentration of the dye is rapidly changing it is difficult ot representative samples.

T Dotter (Portland) showed how angiography had d in the diagnosis of cases of congenital heart-disease

Surgery of Mitral Valve Disease

E Harken (Boston) dealt with the surgery of mitral disease In the very seriously ill operative mortality is very high (28%) but in the less severely ill mortality fallen from 14 to 3% It is likely that the mortality be still further reduced if emboli can be prevented A ier improvement has been to avert disturbances of water sodium metabolism during the postoperative period preoperative recognition and the surgical treatment of al insufficiency remain difficult Harken is attempting to ce mitral insufficiency by fixing a plastic bottle under the al valve 24 such operations have been done on severely tients. There were 7 operative deaths. 11 patients have ved for two years after operation, and 5 were greatly oved by the operation There is no evidence that the closes up after valvotomy though the myocardium may In discussion C W Borden stated that a stenosis which l be widened had been found in 4 patients with massive ation of the left atrium.

C. Bigelow (Toronto) showed how surgical treatment of al stenosis had had a favourable effect on the course of disease L Dexter (Boston) is impressed with the er of continuing rheumatic activity and recommends aylactic penicillin routinely after operation.

Approach to Aortic Valve

P Glover (Philadelphia) showed how the aortic valve much more difficult to approach than the other heart s. To go through the left ventricle is not easy and the ion leaves the myocardium in a weakened condition The oach to the valve through the aorta has not been success He favours the use of an expansible dilator introduced the left ventricle If the patient can be operated on e florid calcification occurs, so much the better During years 23 patients have been operated on ; 3 showed lent results, and 9 were improved (though 3 of these quently died) ; 2 were unchanged and 8 died

A. Hufnagel (Washington D C.) described his method e introduction of a plastic no return valve into the aorta tients with aortic insufficiency 20 patients have been ted on, and 15 are living and improved ; in the last 10 there has been 1 death from myocardial failure He considered the possibility of treating aortic stenosis by rting it into a regurgitation and treating that.

Heart lung Apparatus and Hypothermia

H. Gibbon (Philadelphia) described the application of a anical heart lung apparatus to cardiac surgery The for such an apparatus arises because cardiac defects ot always be dealt with satisfactorily unless the lesion e seen and there is adequate time for its repair Lowering ody temperature permits an increase in the time over h the circulation may be stopped but the time available ll short and the procedure is not without danger For een years Gibbon has been developing a mechanical lung apparatus. On May 6 1953 the objective of these of work was attained when the apparatus took over the ation for twenty-six minutes during the closure of an septal defect in an 18 year-old girl

D Dodrill (Detroit) described how the blood-stream be diverted from either side of the heart. He had that one lobe of the lung could suffice for respiration, at blood from the pulmonary vein could be pumped into ubclavian artery on the same side. With this diversion e circulation mild hypothermia might be used In the ary of the discussion Dr Gibbon said that it might inadvisable to cool adults below 32°C.

G Bigelow (Toronto) had found that with cooling of imal the oxygen requirement steadily declines until at it is approximately 15% of normal Young animals tand cooling better than old ; there are marked species nces, and investigations of hibernating animals are being d out At 21 C a distinct change may occur and circu failure may suddenly develop Anti histamine drugs aid the fall in temperature and the compound Win 2 173 may prevent the severe bradycardia. In Toronto cooling to 30°C has been successfully used to aid a patient with mitral stenosis and congestive failure through a valvotomy Rewarming is done by immersion in warm water or by means of a radio frequency inductive machine

F J Lewis (Minneapolis) preferred cooling the animal by diverting a portion of the blood-stream through a cooling coil 6 patients had been subjected to hypothermia during the repair of an atrial septal defect Of these 2 had not survived the operation, and 1 had died suddenly on the third day Air embolism was prevented by continuous aspiration of the left ventricle and defibrillation satisfactorily dealt with by electric shock and cardiac massage Hypothermia had also been used in the excision of a tumour of the *liver R J Bing thought it possible that when the* heart was cooled anoxia of the myocardium might occur because the reduction in coronary flow might exceed the reduction in oxygen metabolism.

Atrial Septal Defects

C. Crafoord (Stockholm) described the techniques of selective angiography of the heart and great vessels He showed how the left atrium could be punctured directly if a needle was pushed in from above the 9th rib on the left side posteriorly Occlusion of a pulmonary artery by means of a cardiac catheter bearing an inflatable balloon had been used to test whether a lung could be resected when the opposite lung was also diseased Lastly he described a Danish operation for closure of an atrial septal defect in which the right and left atria are separated along a line of cleavage between them as far as the rim of the defect which is then closed by sutures.

H Swan (Denver) discussed the various methods for the closure of an atrial septal defect. In his laboratory a closed method has been developed in animal experiments but for patients he favours the use of a visual method in an open heart during hypothermia When the atrium is stretched by the tapes occluding the superior and inferior venae cavae the walls of the defect come together and surgery is facilitated Air embolism is avoided by tourniquets round the lung roots and flooding the chest with saline before closing the heart In one operation the circulation was stopped and the defect closed in 7 minutes 50 seconds

Pulmonary Stenosis

W J Potts (Chicago) considered the surgical treatment of pulmonary stenosis. When a ventricular septal defect is associated with the stenosis the malformation may be treated either by a shunt operation or by a direct attack on the stenosis He favours the shunt operation because the mortality is lower and the results equally good An aorta/pulmonary artery anastomosis is done if the aortic arch is on the left otherwise a subclavian pulmonary anastomosis is done In children below three years of age the operation is done as an emergency operation ; the mortality is high (15%) but in 192 older patients the mortality was only 3 1% Pulmonary stenosis without ventricular septal defect is treated by incision and dilatation of the pulmonary valve

Physiology of Congestive Failure

W F Hamilton (Augusta) in the George E. Fahr lecture showed that a simple theory that disturbance of the balance between capillary filtration pressure and plasma oncotic pressure caused cardiac oedema was inadequate Salt balance renal hæmodynamics and hormonal changes must certainly be considered He had studied the problem in dogs whose left atrium had been narrowed by means of a ligature If the ligature is tight enough these dogs develop distinct ascites, which disappears when the ligature is slackened No leg oedema occurs and this is thought to be due to the development of collateral circulation The pressure in the abdominal veins is not high and apart from an increase in paralobular veins, the liver appears normal Plasma protein and sodium are both reduced and the renal creatinine and P.A.H. clearances are both low The condition, which is ameliorated by giving carboresin, is thought to be comparable to congestive cardiac failure Investigations of the effect of the adrenals and the pituitary on the condition are still proceeding

Special Articles

SURVEY BY THE MINISTER

At the annual meeting of the Executive Councils' Association (England), at Torquay, on Oct 7, Mr Iain Macleod, the Minister of Health, referred to the constitution of executive councils, the continuing shortage of dentists, the heavy cost of prescriptions for drugs, and the improving coöperation between general practitioners and local health authorities

CONSTITUTION OF EXECUTIVE COUNCILS

Mr Macleod said that it had been suggested that the constitution of executive councils should be changed, because the professional members outweighed the lay members In fact there were 13 lay members to 12 professional members, and the real trouble was that the lay members did not always attend as regularly as the professional members In this respect the members appointed by local health authorities appeared to be by far the worst Authorities could appoint outside people, and this should be more often considered

DENTISTS AND ANCILLARY WORKERS

Before the National Health Service began, said Mr Macleod, the Teviot Committee estimated that 20,000 dentists would be required to provide a public dental service The National Health Service had shown that on average each dentist could treat approximately 800 patients a year Taking the present population and making due allowances for all those already toothless, and for the children and expectant mothers who ought to be seen more often than once a year, one arrived at a figure which might well be between 40,000 and 50,000, and this was likely to be far more than the country could afford in terms of both money and man-power

There was not an unlimited number of people of the right calibre to become dentists, and present indications were that it would be impossible materially to increase the present annual intake of about 600 dental students, which was barely sufficient to maintain the profession at its present level of about 10,000 dentists in general practice

> " It is surely but common sense to see whether some of the more simple work now done by dentists with four or five years' training cannot be done by rather less highly qualified workers working under a dentist's supervision But as the law now stands we are hampered here, even in making experiments, by the fact that, with the minor exception of oral hygienists (who scale and polish teeth) working under supervision in clinics and hospitals, it is illegal for anyone other than a dentist or a doctor to do any kind of work in the mouth "

The Government had announced its intention to reintroduce the Dentists' Bill as soon as the Parliamentary timetable permitted This Bill, which was before Parliament last year, included provision to enable experiments, controlled by the dental profession themselves, to be carried out in the training and use of ancillary dental workers who would extract and fill teeth under the supervision of dentists

If as a result of experiments carried out under the Bill, which would necessarily take some years, it were found advisable to introduce ancillary dental workers under careful control, this should enhance the importance and status of the dentist It would give dentists the opportunity of becoming heads of departments in clinics and hospitals where the more simple work might be carried out by ancillary workers under their supervision, with their own much greater skill and experience for the more difficult and interesting cases

" Then we might at least see the end of a many dentists spend more than 50% of their work requiring only a fraction of the skill and they have acquired in their training "

THE DRUG BILL

Mr Macleod declared that the cost of —£46,300,000 a year—was prejudicing many other urgent developments in the National Health He proposed to explain the facts to doctors and their help, and to supply them with all the he could to help them to help him in keeping cost of the drug bill He had just sent to all practitioners a list showing the prices of all remedies and of their standard equivalents, and suggestion of the British Medical Association the medical officer of the Ministry was appealing appropriate medical authorities to see whether information on the cost of prescribing could not in the course of medical education Executive might be able to help by taking advantage of opportunities to explain to the public the using the health service sensibly and to point patients must not expect doctors to prescribe for whatever they thought they ought to have particular, household remedies for self medication things patients were expected to buy for th

GROWING COOPERATION

Special reports from local health authorities shown growing coöperation between general pra and these authorities

At *York* three general practitioners asked for to be allocated to attend antenatal clinics run for patients in their own surgeries, and this has been by the local health authority

At *Wolverhampton* a coördinated scheme of based on a somewhat similar procedure has been between the local health authority and the local practitioners which should result in the best use being of the facilities provided by the local authority's clinics and of the services of the doctors

At *Gloucester* a special nursing service has been to relieve general practitioners of night visiting for the of, for example, giving subcutaneous injections

In *Staffordshire* a scheme is now in operation in of the county by which the general practitioner chronic sick case, which he considers cannot be home under prevailing circumstances, to the area officer, who then tries to make suitable arrang the patient to remain at home through the provision of nurses and home helps This has resulted in many being nursed at home who would otherwise be rem hospital

The need for a social worker in the general prac team had already been voiced When one looked field covered by the local authorities in their as local health authorities and " welfare " au one found a wealth of resources waiting to be including visitors to the blind and visitors physically handicapped in one group, the duly au officers and mental health workers in another, and third a wide range of arrangements for the often by voluntary workers, of old people, largely by the Old People's Welfare Co was here that the right type of social worker perhaps be found The first step was a proper between this great band of welfare workers general practitioner—a process which in a few had already started but which needed to be much further The Minister said he would like the social worker as a member of the general prac clinical team—particularly valuable in helping care for the unmarried mother, handicapped the old people—and to develop the closer link up he social and welfare functions of the local authority ch ought to be regarded as complementary parts of service to the public

MEDICAL PROTECTION SOCIETY

DDRESSING the annual meeting on Oct 7, Sir ERNEST K CARLING, the president said that last year the ety had received more than 2000 requests for advice revised rules for coroners, which the society's esentatives had helped to formulate, were now in ation, and he believed they were proving successful giving evidence at inquests pathologists should, he ight, take care not to express opinions on clinical ters, as they had recently been doing in one or two ts. The pathologist had the advantage of being wise r the event but was exempt from the responsibility eciding what treatment the patient should have while alive. Coroners therefore should not attach impor e to the clinical opinions of pathologists who spoke side their proper province. As regards complaints patients negotiations were in progress with the istry of Health concerning the procedure under h hospital authorities were enjoined to indemnify nselves by putting the responsibility on members of r staff (So far had this procedure been carried in one case the hospital authority, in repudiating ility on its own behalf presented the plaintiff's itors with a series of points in which, as it alleged, the ndant doctor had been negligent—and of course the itor for the patient adopted these allegations in an nded statement of claim) Sir Ernest had reason to eve that in the very near future a modus vivendi would reached enabling hospital authorities and hospital s to collaborate fully over claims made against them unsatisfactory relation between doctors and hospital orities was bound to react in some cases to the iment of the patient.

he provisionally registered doctor was now entitled, all other registered practitioners, to all the services he society To practitioners not yet provisionally stered, however no indemnity could be offered gh the society's advice was at their disposal This ation was really rather serious because many hos ls had no house-surgeons or house-physicians at all ne region there was a shortage of 100 housemen in another a shortage of 60 Lacking housemen hospitals employed students and the responsibility with those who employed them The newly qualified could not, in some cases take one of these vacant s because they were not recognised as suitable for training of men seeking provisional registration

he President regretfully noted the continuing ten y to increase the amounts of damages awarded by courts. If this continued at the same pace the iety's annual subscription—so reluctantly raised— ht have to go up further

r W M MOLLISON, the treasurer, said that, at over ,000, costs and damages paid on behalf of members year amounted to £5000 more than in 1951 but raised subscription enabled the society to show a urable balance of about £8400 on the year's working er paying a tribute to the work of Mr S Rayner society's financial secretary Mr Mollison drew ntion to the cards sent out with the annual report tled Statutory Notifications to Public Authorities Reporting Deaths to Coroners. These summarised facts admirably and their usefulness to final year dents had already been recognised by medical schools ch had ordered supplies.

he President and Treasurer were re-elected for a her year and Dr Alistair French received warm nks for his services as secretary to which office he was re-elected Appreciation was also expressed of work of Miss Remington as assistant secretary and Messrs le Brasseur and Oakley the solicitors, whose esentative Mr W G Hawkins addressed the meeting vote of thanks to the President was proposed by F Harwood Stevenson chairman of council.

The annual report, issued by the M.P.S. from Victory House Leicester Square London W C.2 shows that the society has continued to make steady progress and at the end of last year had a membership of 27 960 With resources exceeding £156 000 and reinsurances with Lloyd's under writers its financial position is strong and the council are satisfied that it can meet any demands which members may make Members are encouraged to consult the secretary on any medico-legal or ethical problem affecting their professional work, character or interests" and, as usual they are asked to bring their difficulties to the society *at the earliest possible stage*

GRADING OF S.H M O s

THE following statement concerning review of senior hospital medical officer gradings has been issued by the British Medical Association:

At the annual representative meeting in July 1952 considerable disquiet was expressed regarding alleged injustices following the review of S.H.M.O.s which had taken place some months earlier and a plea was put forward that there should be a right of appeal to some central body against decisions of the review committees. As a right of appeal had previously been refused by the Government the Central Consultants and Specialists Committee did not feel that any useful purpose would be served by pursuing the matter but the committee gave an undertaking that the committee would raise individual cases of apparent injustice with the Ministry

The committee subsequently examined the claims of those S.H.M O.s who had expressed dissatisfaction with their grading and sought advice from independent sources. As a result the committee was satisfied that there was prima facie evidence for suggesting that in certain cases injustice had been done and these cases were brought to the notice of the Ministry The Ministry replied that the status of all the practitioners originally graded as S.H.M O.s had been thoroughly reviewed on more than one occasion and that it was clearly under stood that the review at the end of 1951—the machinery for which had been agreed with the Joint Committee—would be the final approach to the problem The Ministry stated that it was always ready to satisfy itself that in any particular case the proper arrangements had been made for the review of grading and it had ascertained that in each case to which its attention had been directed the fullest consideration had been given by a committee which was expert, locally informed, and constituted in the agreed manner The Ministry thought that no central appeal committee could enjoy all these advantages and it saw no reason therefore for reopening the question.

The matter was thereupon taken up by the Joint Committee which informed the Ministry that while it did not doubt that the review committees had been properly constituted it did not feel that the possibility of error should be ruled out. The Joint Committee stated that in its view the cases to which the Central Consultants and Specialists Committee had drawn attention provided evidence of mistakes in grading sufficient to justify further investigation and it urged that they should be examined again

The following reply has now been received from the chief medical officer of the Ministry

> I promised to consider further your suggestion of an informal meeting with documents to discuss the grading of certain Senior Hospital Medical Officers. I have now done so in the light of what was said at that meeting and on previous occasions when we have discussed these matters of grading
>
> I must say after the fullest consideration that we are unable to accept the suggestion of a further review of these gradings. The review in 1951 was entrusted with the agreement of both sides to specially constituted professional committees and was accepted by both sides as final I cannot see how we could justify questioning the decisions of these committees which were made on that understanding and have now been put into practice It seems to me it would greatly increase the difficulty of ever making any settled arrangements if matters so definitely and finally decided could be reopened.

In England Now

A Running Commentary by Peripatetic Correspondents

We have a medical friend who has several times credibly informed us that he had never had his opinion publicly polled, and when we met him the other day he was at pains to tell us that this stigma had now been removed The great moment arrived as he was sitting peaceably in the Union Station in mile-high Denver, waiting for the Rocky Mountain Rocket to bear him away to Chicago He tells us he was approached by a young lady bearing a bulging despatch case, who sat down beside him "I'm not trying to sell anything" said the young lady hastily, with a trace of discomposure, "I'm a public-opinion poll, and would you care to answer some questions?" Our friend was at once in the picture, and leaned forward eagerly, his tongue trembling with the urgency of his opinions on mile-high Denver, Senator McCarthy, the British National Health Service, and the decadence of the Broadway theatre

The young lady opened her bag and with difficulty extricated a large pile of dilapidated trade periodicals with titles like *Aluminum* and the *Precision Blockmaker's Weekly* "There," she said, "have you read any of these in the last week?" Our friend admitted his oversight, but excused it by his foreign origin "My!" exclaimed the young lady, "to think I'm listening to the tongue Shakespeare spoke! It always gives me a kinda cold feeling right here!" She indicated the back of a shapely neck, and gazed in admiration at our friend, who had not appreciated his linguistic capabilities in this light before It was with difficulty that the young lady remembered the rest of her mission, and produced for our friend's inspection a number of packs of cigarettes of all degrees of magnitude from Bantam to King size Our friend was forced to admit that as a non-smoker he could offer no constructive opinion on them, and the poll was over, leaving behind it on both sides a sense of mild frustration

Determined that the young lady should have his opinion on some subject, our friend hazarded his belief that taking public-opinion polls in the Union Station in mile-high Denver must be an arduous occupation His interlocutor agreed "But you should see me next week," she said, "I'm doing girdles and bras"

To his lasting regret, our friend couldn't make it

* * *

I once went to a lot of trouble studying foreign languages and now I wish I hadn't The aged chambermaid of my small hotel has just given me a twenty-minute recital of her symptoms She has told me about her rheumatism, her mother's rheumatism ("This as a doctor you will find interesting"), the state of her digestion, and the effect of various articles of diet thereon She told me how she found herself a little weak, and she had only seventy-five years She thought she might have a *Krebs*, but her doctor thought not What did I think the pain in her back could be due to? Then she thought it perhaps might be the *Verstopfung* under which she always suffered bad Sometimes to eight days I took avoiding action by assuring her that of the *Todesscheinen* I had written, not one single had been on account of *Verstopfung* She seemed relieved, but I shall get more later

Before the war this wretched half-knowledge of tongues was always getting me involved with foreign officials, usually for bringing the wrong money into their countries sometimes for taking it out They always spoke their own language better than I did and argued me off my feet Often have I cursed my stupidity in not putting on the blank exasperating expression of the honest monoglot Englishman who wins every time without opening his mouth Another way out of course would be to speak the language as well as the natives, but if any true-born Englishman can do that he has no business to After such humiliations I find myself taking comfort in the opinions of my great-aunt long deceased She held that there were two sorts of people in the world, ourselves and foreigners By some strange error of Providence many of the most famous cathedrals, museums, and picture galleries were situated abroad, and one could not visit them without meeting though one would naturally meet as few of th possible They were strange people who seldom English properly Their way of life was insanitary morals unmentionable, and their habits distasteful. were always having wars with one another, and we English out of goodness of heart sometimes allowed ourselves to be drawn in

And then of course they could not make tea.

* * *

It is a source of continual humiliation to me I cannot learn the dosage of penicillin Only they came and told me that one of the monkey sick and asked me to write out a prescription "Penicillin," they said, "that's what it needs" I they had said quinine, now, or morphine, or ma I would have had a firm grip on the situation

The fact is, I am a pre-penicillin man. When pharmacology it was at the feet of a muscular and preceptor who insisted that morphine and mag were the only two drugs a doctor needed But e those happy days my security was being undermi the manufacture of 'Prontosil' or some such stuff (I never did find out the dose of that either)

I am a dead loss to the drug houses. Every m a shiny surrealist picture arrives advising me passing of yet another pharmaceutical mil *safe* brand of succinylcholinesterase an I no longer even turn pale At the mention of barbitone something stirs dimly in my subcon but it goes again directly I can see that my despise me When they decide they need a to look at me contemptuously and say "I suppose good asking *you*, is it?" before they dash along chemist They are quite right, it isn't

Come to that, I am a pre-electrolyte man too wasn't all this nasty sodium about when I was But then again, when I studied medicine people own blood-groups and stuck to them, and you smoke all you wanted without the statisticians at you

All this, of course, is sour grapes. I envy heartedly those gifted souls who can dash off an "rep mist" with a flick of the wrist in the full co that the chemist won't ring them up and have a little chat with them Chemists always ring me about the monkeys I can picture them sniggering to themselves behind their green and red bottles they dial my number "About that pres doctor," they say apologetically, "it's for three l lethal dose I thought perhaps I'd better check you"

It is possibly just as well that my therapeutic is now confined to monkeys But I wish they always need penicillin

* * *

THE NEUROLOGIST'S LAMENT

Long pants!
Do they *all* have to wear them?
Long pants!
Don't they know I can't bear them?
Gastrocnemii hidden—no A J.s I see,
I can't get within striking range of the knee,
And how *can* I, I ask you, test pain at L3?
Long pants!

Long pants!
Roll them up a bit, do Sir!
Long Pants!
Stop! Your leg's turning blue, Sir!
My physical findings could not be much vaguer—
"Vibration sense doubtful six inches of Jaeger"
And how can I tell if the chap's got lumbago!
Long pants!

Long pants!
What if Dad always wore them?
Long pants!
Can't they see I abhor them?
Corsets I cope with, and bras I can master,
I've examined abdomens through holes in a plaster
But if anything courts diagnostic disaster,
It's—LONG PANTS!

Letters to the Editor

ORTISONE IN RHEUMATOID ARTHRITIS

ı,—For some time we have felt that patients and public are being given on the whole an unduly urging view of the use of cortisone and cortico in (A C T H) in rheumatoid arthritis. The publicity by the *Times* of Oct 2 to some rather pessimistic ments *in the October issue of the Practitioner* leads offer our own more hopeful opinions

the *Practitioner* Dr William Tegner points out that sone can have a profound and gratifying effect in ressing the activity of rheumatoid arthritis but he says that after early hope and optimism, dis intment inevitably follows.' From more than three of experience during which time we have returned previously incapacitated patients to an active life latively small doses we regard this second statement o strong No doubt prolonged treatment may with it a host of difficult and even dangerous effects, such as addiction fluid retention cardiac rrassment and mental change' but the art of ine lies largely in obtaining the effects desired t avoiding unwanted sequelæ and cortisone is far being the only drug which is capable of causing Admittedly it is more difficult to use properly was at first hoped, and this has discouraged many ians, on both sides of the Atlantic But we have l it possible to achieve success in a majority of if enough time and trouble is taken.

his *Practitioner* review of advances in medicine D M Dunlop *points out that* when *cortisone is* quiescent infections such as tuberculosis may be ed hypertension made worse or a rebound of rthritis occur on stopping treatment Certainly all possibilities should be well known to anyone using one or A C.T H Such infections must be excluded *e cortisone* or A C T.H treatment is considered for are absolute contra-indications to its use. Also ment never should be stopped abruptly but tailed very gradually

ofessor Dunlop goes on to say that in rheumatoid itis "there is some evidence that in the long run ultimate state of patients controlled by cortisone is etter than those controlled by adequate doses of in' This amounts to saying that both drugs ess but do not cure the disease We would agree in those cases where such suppression can be iately produced by aspirin this should always be lrug of choice it is only in cases where simpler fail that cortisone is indicated His advice that ore using cortisone it is necessary to balance carefully the beneficial effects against the which its use involves is surely applicable to the f any powerful therapeutic substance On the other Dr Tegner's statement that the early beneficial may need progressively larger doses for its tenance' is contrary to our own observations.

believe that the present status of cortisone and H in the treatment of rheumatoid arthritis would iore accurately stated as follows These drugs itute the only quick acting therapeutic weapons ssess with which we can in many cases completely ress the signs and symptoms of this disease They ot applicable to all cases and indeed candidates ich treatment must be carefully selected for there nany known contra indications These substances ery far from foolproof and considerable experience eir use is required if good results are to be main d Patients on such treatment must be constantly ved for their therapeutic needs and responses may rapidly We fully agree with Dr Tegner that such ment should be associated together with the other basic forms of treatment designed to prevent deformity and never as the sole therapeutic method

SMOKE AND SULPHUR

SIR —Being concerned with the efficient domestic use of solid fuel, I was greatly interested in your leading article last week and should like to make some observations on a matter of fundamental importance to the problem of atmospheric pollution

It is in many ways unfortunate that the National Smoke Abatement Society—whose work merits all possible support—should have the title that it has and that campaigns against atmospheric pollution and those against smoke should be confused in the public mind. If smoke abatement campaigns and smokeless zones are designed to reduce the amount of dirt in the atmosphere, they are well conceived It must however not be assumed that they are at the same time reducing the toxic elements derived from the combustion of coal or other fuels

It is clearly appreciated by medical opinion that one of the most probable causes of increased mortality from fog is the high concentration of sulphur dioxide and sulphuric acid in a foggy atmosphere. Indeed support *for this view is given by the paper on the effects of inhalation* of sulphur dioxide also published in your issue of Oct 10 If this is the case the danger to health from fog will not be removed by the establishment of smokeless zones by the burning of solid smokeless fuel, or by the use of electricity (Gas from which sulphur has been largely removed, is in a different category) *Indeed it* may well be that the greatest single factor increasing danger from fogs in London lies in the erection of vast new power stations in the Metropolitan area

Since all solid fuel commonly consumed whether in industry at power-stations or on domestic hearths, contains a greater or less proportion of sulphur the only way in which the emission of oxides of sulphur into the atmosphere can be reduced short of installing elaborate plant for washing flue gases, is by reducing the consumption of fuel

In the domestic sphere this has already been done in that the present annual domestic consumption of solid fuel has, as a result of restrictions been reduced by about 15 million tons, compared with the pre war figure Over the same period coal burnt in electric power stations has increased by some 20 million tons.

It is high time that the indictment of the coal burning domestic grate as a major cause of atmospheric pollution should be critically re-examined While the supply of smokeless fuel remains at a substantially unchanged level, the main effect of the creation of smokeless zones will be to shift the incidence of smoke from one part of the country to another In the process, their establishment will not significantly reduce the amount of sulphur oxides discharged into the atmosphere

ERIC BELLINGHAM
Director-general,
Coal Utilisation Council.

London S W 1

THE WRONG BLOOD

SIR,—Your leading article of Aug 1 discusses accidents in blood transfusion To illustrate their causes you give five examples of human carelessness—I should myself call them administrative mistakes'—but only one example of a technical error by an uninstructed technician *It strikes me therefore as a little illogical to insist* that 'transfusion must be under the direct control of a senior pathologist Of course I appreciate the implied compliment to senior pathologists—that they alone are reliable enough to be trusted with such things But I still feel that since blood *transfusion* is a form of treatment it should be left to a clinician The pathologist should administer the blood bank but otherwise he should be responsible only for grouping and matching He might well use the following formula for his report

> "The red blood cells obtained from a sample of blood labelled with the name received at
> on have been tested and found to belong to group Serum from the same sample of blood failed to agglutinate red cells from (a) bottle(s) of stored blood of group numbered "

and there his responsibility should cease

BACKFLOW IN RETROGRADE PYELOGRAPHY

SIR,—I was very interested in your annotation (Sept 19) on this subject, which was discussed at the annual meeting of the British Association of Urological Surgeons in Edinburgh in 1951, and was reviewed last year[1] The findings agreed in the main with the subsequent work of Kohler[2] to which you refer but there are some points which, I think, merit discussion

You state that in retrograde pyelography backflow, or penetration of contrast medium beyond the confines of the renal pelvis, has been estimated to occur in anything from 4 to 25% of examinations This figure is perhaps rather high In 1876 reports of retropyelographic examinations, I found it in only 2%[1], and in a further personal series of 547 retrograde pyelograms in 282 patients, I have found the same percentage—2 This is a much lower figure than Kohler's 154 cases of backflow in 628 routine retrograde pyelograms

Pyelorenal backflow is essentially a traumatic, pressure phenomenon, leakage of the contrast medium injected up the ureter occurring at the calyceine fornix angle into the renal sinus fat and into the tributaries of the renal veins, as has been shown by the investigators mentioned in your annotation, and particularly by Hinman[3] Many urologists, therefore, when injecting contrast media up the ureters use a funnel and rubber tube and run it in by gravity The pressure used in injecting with the hand syringe is surprisingly high, and Hinman and Redewill[4] noted how easy it is to produce high pressures—even up to 200 mm Hg—very quickly You mention that Kohler describes his findings in 27 patients in whom he performed retrograde pyelography, recording the pressure in his syringe with a manometer in circuit I have now records of 547 manometric readings in 282 patients (142 males, 140 females) My findings are very similar to Kohler's Pain is not a reliable guide to the state of filling of the renal pelvis during retrograde pyelography Some patients tolerate pressures of over 100 mm Hg without discomfort, some have severe discomfort at 20 mm The appearance of backflow is a variable phenomenon, occuring at a pressure as low as 25 mm Hg, and pain may or may not accompany it

Kohler divides backflow into three types (*a*) sinus extravasation, (*b*) pyelotubular backflow, and (*c*) a mixture of the two He also mentions the streaks passing medially from the kidneys, seen in some pyelograms These appearances were originally considered to be due to pyelovenous backflow, but Higham[5] pointed out that they were more likely to be lymphatic Kohler and the majority of other modern observers tend to think that most of the published cases are, in fact, examples of lymphatic spread They continue to be, however, something of a puzzle

It is, as you mention, quite easy to inject the renal vein via the ureter in cadaver specimens, and a cast of the renal vein is readily obtained by injecting 'Neoprene' into the renal pelvis That being so it is reasonable to suppose that, in some of the cases showing fine streaks passing medially from the kidneys in certain pyelograms, the appearance is due to venous backflow, particularly as the arch shaped streaks seen running between the calyces are usually prominent in these cases The arch shaped streaks are usually taken to be dye actually in the arcuate veins, which lead to the main renal vein

On the other hand, the "beaded" appearance of of these streaks, and their position—passing in front of the lumbar transverse processes—strongly that they are lymphatic channels Kohler's observ the appearances persisted in his cases for three to five and that there was no fluorescence at all in those patients were tested, tends to confirm the "lymphatic" view K use of fluorescein sodium with the contrast medium is a most valuable contribution to the investigation of phenomenon Until lymphatic channels can be dem demonstrated by dissection in injected cadaver sp however, there will remain some doubt as to t or causes, of the appearances

In this country Williams[6] distinguished the vari pyelorenal reflux from the radiologist's point of view (1) pyelovenous, (2) pyelolymphatic, (3) pyelotubular (4) pyelo interstitial extravasation Combinations of varieties may occur in the same case This classifi more comprehensive, and more useful, I think, than th

The possibility of backflow in retrograde pyelo should warn all those performing this investigati inject the opaque medium up the ureter as gen possible into that really porous organ, the kidney Ogier Ward made a particular point of this in F Moore[7] has described some of the more serious co cations arising from this investigation, but the degrees of penetration of the medium beyond the c show how easy it is to damage the kidney Gent pays therefore, and the more careful one is forming retrograde pyelographic examinations, the cases of backflow will be seen The subject of pyel backflow is of great interest, and is linked with problems of renal physiology and pathology— nephrosis, for instance There is plenty of sco further research here

JAMES A R

EMPLOYMENT OF THE DISABLED

SIR,—Your annotation of Sept 19 leads me to m the results of a small survey on disabled young w conducted in Birmingham;[8] among 54 firms and co 140 disabled young people, which contrasts to extent with Ferguson's findings in Glasgow[9]

In 1951, Birmingham, in a period of full emplo offered a wide and varied selection of work opport in light industries Disabled young people (exc epileptics) had no more difficulty in finding jobs their able bodied counterparts During this p disabled young people were able to change their j working conditions were unsuitable, and in fact d hesitate to change jobs for more trivial reasons therefore not surprising to find that, although in half of those leaving their jobs the reasons given connected with their disabilities (such as uns work, nervous strain, and noise), only one young was found actually to be doing work unsuited t physical capacity He had taken his job without th of the Youth Employment Bureau and without acq ing his employers with the fact that he suffered cardiac disease

On the other hand the inadequate number of di young people receiving suitable training in B certainly bears out the Glasgow experience out of 140 were actually apprenticed, of 31 in tra the boys were engaged in the electrical, optical, glass jewellery trades and the girls in dressmaking embroidery Of both sexes 36 were engaged in cl work, the others were in semi skilled jobs limited prospects of advancement Of 11 firms t survey which had apprenticeship schemes, 2 had accepted disabled youngsters and 4 more were wi take them Of the 5 firms which refused, 4 did so

CYNTHIA WALTON

FREEDOM TO PRESCRIBE

—Your annotation of July 25 has been brought o notice of the Northern Ireland General Health ces Board

e Board are in full agreement that matters of public est and matters affecting the public purse should be presented to the public and it has, therefore always the policy of the Board to afford full opportunity to sentatives of the press to attend Board meetings and t such matters This policy was not departed from e case to which you refer Your annotation was, ver based apparently on articles which appeared in ress on June 25 and which reported only the dis on at the Board meeting on the previous day and ot give the full picture up to that date

u will appreciate that from time to time matters for discussion the publication of which at that might be undesirable and it is, of course the ice to consider such cases in camera. All Board Committee minutes when confirmed are however available to the press and the only matters which xcluded from the minutes for this purpose are those h are clearly unsuitable, in the interests of the ces, for publication

pursuance of this policy the decision of the special mmittee was discussed in camera but was made able to the press in the minutes of the meeting of the d at which the discussion took place I am not e that the decision was published by the press and, our information, it was to the effect that the Committee were satisfied that the Board, in acting upon the o of their professional committees and in accepting the decisions of the Central Medical Committee had taken the only action possible in the circumstances

The Board have instructed me to furnish you with the accompanying statement giving some examples of the prescribing of Anahæmin ' 'Examen and Oral Liver Extract by the doctor concerned. In accordance with regulations in Northern Ireland it is the Board s duty to submit to a statutory Committee nominated by the medical profession here and known as the Central Medical Committee cases of apparently excessive prescribing The Board having regard to the views expressed by the Medical Research Council and the manufacturers of anahæmin have felt bound from time to time to regard this doctor s prescribing as in excess of what was reasonably required for the treatment of his patients They accordingly submitted cases to the Central Medical Committee which committee after investigation and having afforded the doctor full opportunity to justify his prescribing determined that the prescribing was excessive and assessed the amounts of excess These amounts have been recovered by the Board from the doctor

Northern Ireland General Health Services
Board 9 Upper Queen Street
Belfast.

G D STEWART
Secretary

Quantity		Period (days)	Approximate daily dosage		Cost	Amount recovered from doctor
Anahæmin or examen (ml.)	Oral liver extract (oz.)		Anahæmin or examen (ml.)	Oral liver extract (oz.)	£ s. d.	£ s. d.
610	—	10	26 84	—	40 2 9	40 2 9
1625	400	227	7 16	1 77	2[illegible]3 1 11½	211 0 1
2340	24	44	53 2	0 51	190 8 3	182 5 10

950	—	13	73·07	—	85 7 8	—

above cases A B and C, were heard by the Central Medical ittee, who decided that the prescribing was excessive and mined the amount of the excess. In case B the doctor appealed ependent referees appointed by the Ministry of Health and Government who upheld the decision of the Central Medical ittee Cases D and E have not yet been decided by the al Medical Committee

154 of the doctor's prescription forms dispensed in July by ts in his area, 87 or 56½% were for liver preparations

e figures exclude the charges payable by the patient and present the net cost to the Board

EFFECT OF PENICILLIN ON PINK DISEASE

SIR,—In each of the following two cases penicillin seemed to have a striking effect on pink disease

CASE 1—A girl aged 13 months, was first seen on Aug 8 1951 with bronchopneumonia and pink disease She had previously been diagnosed as a typical case of infantile acrodynia at the Royal Hospital for Sick Children Glasgow with a history dating from May 2 1951

The child was thin listless and miserable and remained in the position associated with pink disease There was diffuse bronchopneumonia and typical eczematous lesions of glove and stocking distribution. Distaquaine penicillin was given intramuscularly for six days, and Anthisan cream was applied locally to hands and feet

CASE 2.—A girl aged 2 years 11 months was first seen on Nov 25 1951 On Dec. 5 she was treated with distaquaine penicillin for an incidental throat infection, after which her general condition appeared to improve Subsequently she was admitted to Weymouth and District Hospital where the diagnosis of pink disease was confirmed Because of the general improvement after the penicillin therapy for tonsillitis oral penicillin 200 000 units four times daily was commenced on Jan. 8, 1952 and continued until Jan. 21

Both these cases conform with the classical description of pink disease [1] and both improved considerably during and after penicillin therapy The patients appeared normal on cessation of treatment and have since remained so

Chloramphenicol is reported to have brought about apparent cure in two cases of pink disease [2]

It is known that antibiotics may improve the availability of vitamins of the B group: megaloblastic anæmia of pregnancy has been successfully treated by penicillin alone [3] and aureomycin can increase the availability of vitamin B_{12} administered orally in cases of pernicious anæmia [4]

Antibiotics may alter the intestinal flora for example aureomycin in high doses can effectively remove bacteria from the human gut [5] and dietary streptomycin has been shown to cause an increase in *Bacillus megatherium* (known to synthesise vitamin B_{12}) in the gut of the mouse [6,7] Penicillin prevents depression of growth in poultry probably by altering the bacterial flora and

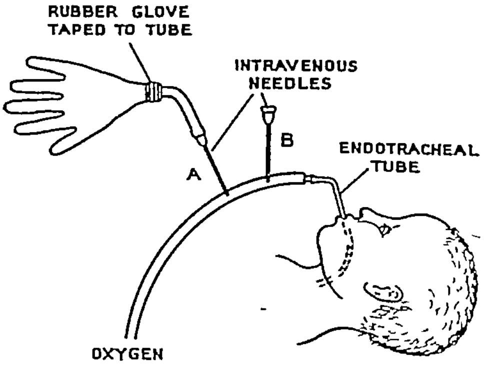
ASPHYXIA IN THE NEWBORN

SIR,—For the immediate and certain relief of asphyxia of the newborn, endotracheal intubation followed by inflation, using a rebreathing bag, is a method which is not, I think, used sufficiently

It is wise to remember, as Eastman[9] has pointed out, that "in the presence of anoxia, apnœa is resistant to all types of treatment other than correction of the anoxia itself Even convulsive doses of nikethamide have no effect on anoxic apnœa, on the other hand, a few insufflations of oxygen produced immediate breathing"

Quite often, however, there is a mechanical barrier in the way of the all important oxygen Sometimes this takes the form of a thick matted curtain of mucus I feel that endotracheal intubation is justifiable only after pharyngeal toilet has been carried out under direct vision Quite often this mucus barrier can be demonstrated at this stage Pharyngeal toilet has to be done anyway, as the intubation is completed under direct vision

If it does nothing else, laryngoscopy of the newly born demonstrates the futility and inefficiency of the mucus catheter in common use A good deal of misunderstanding appears to exist about the trauma involved in this procedure of intubation Naturally the disturbance is a matter of degree and is related to the skill of the operator A size 0 tube is used, either all rubber or armoured with a wire spiral embedded in the rubber Plastic tubes are easier to introduce, but the fairly thick walls of the tube reduce the lumen



Semiclosed circuit for insufflation of newborn

Writing on artificial ventilation of the lungs, Professor Pask[10] evidently prefers efficient artificial respiration to inadequate spontaneous respiration, for he remarks "Positive pressure ventilation can be carried out without causing disturbance in the cardiovascular system"

Let it be stated quite clearly that there is less shock—much less—than in other methods of artificial respiration Even using a mask alone, considerable force may be used to blow oxygen past an obstruction Intubation is greatly facilitated by a cunningly contrived inclined plane, and the infant need not be exposed, but can be kept well wrapped up

Anoxia at birth is a common cause of small cerebral hæmorrhage—to mention only one result of asphyxia—but it is for the neurologist to assess the late anoxia Nevertheless, the obstetrician is present the neurologist is not, although the latter appreciate more acutely the significance of anoxia though it only lasts a short time

Very occasionally it has been necessary to inflation, at least at intervals, for some time. accompanying figure shows an arrangement which be used when the normal equipment of the machine is not available An ordinary surgeon's makes an excellent rebreathing bag, it is attached rubber tube and sealed with adhesive tape A large needle is needed at A, otherwise an incorrect is imparted to the "bag" The other needle simply a blow-off valve to dispose of carbon dioxide

The most significant clinical feature after through an endotracheal tube is the bright pink the hands and feet which can be achieved few minutes of insufflation

Obviously a device of this kind is easily worked the type of pneumoflator described by Dr Beaver[11]

Watford Maternity Hospital

J NOEL J

POSTURE, BACKACHE, AND HEALTH

SIR,—Few people, even trained athletes and of the Armed Forces, understand the essential of muscle movement and joint control May I attention, for example, to some remarks made months ago (May 1) by The Doctor in one of the he broadcasts on Friday mornings? Speaking backache, he said

> "But fortunately many ordinary backaches are or relieved by the same quite simple measures. The important thing is to maintain the hollowing of the part of your back When standing, stick your out backwards, brace your shoulders back and your back muscles, even if this does mean sticking stomach out a bit"

In saying this The Doctor was advising his to maintain a hollow back by contracting the erector group of muscles Another school advises slight of the spine, favouring a neutral position with the down" instead of projecting the buttocks back

Now our bodies are composed of four main entities attached to fixed parts (a) the head on and trunk, (b) the arm and shoulder girdle on the wall, cranium, and cervical and dorsal vertebræ, trunk on the pelvis, and (d) the whole body attached to the ankles and feet For a movement of the part to be efficient, it must be performed on a firm produced by the active contraction of the prime muscles If in standing a person has all the fixor muscles alerted he or she will adopt a more ape like stance which includes relative flexion of lumbar spine with slight flexion of all other joints

There are three ways of sitting or standing

Inactive —The person slouches or sags, thus the mobile part of the body to put a constant strain the fixed parts

Passive —This is the position of standing The advocates Sagging and forward-flexion strain lumbosacral junction is prevented by placing the of the trunk backwards and making the back through contraction of the erector spinæ muscles position, however, does not fix the lumbosacral lation except by imposing a chronic strain apophyseal joints, which in time tends to osteo-arthritis

Active —This is the ideal First of all the neck as long as possible with the chin tucked in and in a posterior direction Thus the head, on straightened neck, is placed evenly between the in both coronal and sagittal planes The girdles are held up and against the chest consciously neither forwards nor backwards ominal muscles are contracted upwards with the ocks tucked under and knees very slightly bent

‘CHEMOTHERAPEUTIC AGENT’ AND “ANTIBIOTIC”

R,—According to Dr Erwin (Aug 20) chemo py covers treatment by chemical agents and the ble aspirin is of right a chemotherapeutic agent Erwin says that when chloramphenicol was syn sed the use of the term antibiotic to mean a mical substance produced by micro-organisms sman) became obsolete and chemotherapeutic t’ and antibiotic have come to mean the same By this token are we to regard aspirin as an iotic?

e Town South Africa M GLASS

OLINE IN THE TREATMENT OF EPILEPSY

R,—In this colony for epileptics, we have treated t 60 patients with Mysoline’ since September Only 31 however 18 females and 13 males, have observed long enough to evaluate the results Their ranged from 1 to 57 years and the duration of their *s from 1 to 47 years. 24 of the cases capable of* sment were classified as idiopathic and 7 as sympto 24 suffered from both grand mal and petit mal m grand mal alone and 2 from petit mal alone.

e doses of mysoline varied from 0 25 to 2 g daily he commonest dose was 1 to 1 25 g daily Patients started with 0 25 or 0 5 g daily, and the dose was ased once or twice a week A thrice daily dosage ne was commonly used.

soline was used alone in only 2 of the severe cases ilepsy The rest had in addition either phenytoin, oin (‘Mesantoin’) phenobarbitone or Citrulla or a combination of these drugs

7 cases the fits were completely or almost completely olled in 9 there was a significant reduction in umber of fits; in 4 only major attacks were controlled little or no reduction in the number of petit mal ks; and in 1 the number of petit mal attacks ased

soline was more effective against grand mal than mal No difference could be seen in the effect on the athic as compared with the symptomatic, cases ovement was noticed in the mental well being of 10 nts whose fits were controlled They showed less iness and drowsiness and greater initiative

le-effects were seen in 9 patients who showed lent giddiness and sleepiness at the beginning of treatment In 1 patient giddiness and ataxia were quite severe. None of the patients had skin eruptions

The blood and urine of all patients were examined regularly and the only abnormality found was leucopenia in a patient who had shown the same response to earlier treatment with Dimedion’ methoin, and ‘Epidon. Treatment in this case was discontinued

Kolonien Filadelfia,
Dianalund Denmark GUNNAR JORGENSEN

DOSAGE OF ANÆSTHETICS

SIR —In his letter of Oct 3 Dr Galley draws attention to the greater sensitivity to intravenous anæsthetics of the Asian patient as compared to the European In my early experience with Arab patients in the University Hospital in Damascus I was very much impressed by the extreme *variability* in the response to intravenous anæsthesia which made the utmost caution necessary in its use

It soon became apparent however that this variability was due to the existence in the hospital population of three groups of patients with distinctly different ways of life

(1) *The Bedouins: hardy frugal non-smoking and non* drinking nomads in whom arteriosclerosis hypertension peptic ulcer and other diseases of stress are extremely rare This group requires very much less intravenous anæsthetic than the average European it is a particularly dangerous method to use in emergency surgery on Bedouin patients.

(2) The Arabs of the city in this group the habit of life in these days approximates very closely to that of the European and the response to intravenous anæsthesia is not apparently different

(3) The Arabs of the villages: a group in which mal nutrition is common and the hardiness of the Bedouin is lacking addiction to both alcohol and tobacco is not unusual The response to intravenous anæsthetics is intermediate between the two *previous* groups, but cases of excessive sensitivity occur fairly frequently

It must be observed that there are no ethnological differences between the three groups and variations in response to anæsthesia must be the result of factors associated with their differing habits of life The identification of these factors offers an interesting field for research

Our experience with muscle relaxants is that there is no variation in response corresponding to that found with intravenous anæsthetics, although the immediate impression is of an over-all sensitivity greater than that found in Europeans. It has become apparent however that the Arab patient requires approximately the same dose of both Flaxedil and *d* tubocurarine to produce the initial curarisation, but that the duration of effect is appreciably longer than in the European This means a slower rate of elimination and my impression is that in this respect there is not nearly as much variation between the extremes in the groups mentioned above as might be expected from the variations in response to intravenous anæsthesia. We have used Scoline in over 200 cases in patients from all three groups without discrimination and although we have had 1 case of apnœa lasting three hours, the response has otherwise been uniformly the same as with European patients and the dosage required has not been less

While the majority of Arab patients are easy subjects for anæsthesia there is one type of patient which in my experience is more difficult to deal with than any encountered in Britain not excluding the chronic alcoholic and that is the hashish addict These patients combine a resistance to intravenous anæsthesia so great that 2 g of thialbarbitone (Kemithal) given quickly produces no more than drowsiness with a respiratory tract so irritable that the inhalation of any gas causes uncontrollable coughing I find the only way of dealing with them even for minor operations, is to give a full dose of *d* tubocurarine to which their resistance is normal and to force as much cyclopropane into them as possible during the apnœic phase The patients must be watched very closely after operation, for the recovery stage, even after cyclopropane, is invariably most inelegant, with much laryngeal spasm, coughing, and cyanosis In Damascus, hashish addiction is a positive indication for local anæsthesia where this is at all possible

Department of Anæsthesia,
Syrian University, Damascus L T SCOTT

SIR,—From three years' experience in the late war as anæsthetist to a combined British Indian military hospital I can confirm Dr Galley's findings regarding dosage of short acting intravenous barbiturates in Indian and Oriental patients

The average amount required for induction of anæsthesia is about two thirds of that needed in a corresponding European My initial ignorance of this fact nearly resulted in an unpleasant surprise!

I note that in his letter last week Dr Clement advocates Lake's technique for high and mid spinal levels, where spinal analgesia is the method of choice, mentioning that only 9 ml of 'Light Nupercaine' will give satisfactory results for upper abdominal surgery in patients of average size While this is true, I feel that this technique is rather more exacting and less comfortable than methods employing 'Heavy Nupercaine,' using the equivalent of only 4 mg more of the drug

As Professor Macintosh has pointed out,[1] the good and bad effects depend not on the administration of 10 or 15 mg of nupercaine, but on the level within the dural canal reached by the drug

Maidstone A W H ASHBERY

PERIODIC MEDICAL OVERHAUL

SIR,—I was interested in Sir Adolphe Abrahams's points of view (Sept 26) and would agree with him that during medical examination emphasis should be placed on health-mindedness rather than on the possibility of disease I cannot, however, accept so heartily the suggestion that health guidance is not a matter for the doctor and should be handed over to someone else

Unfortunately it is all too true that the training of the medical student and the young graduate has not provided "the best milieu for health-mindedness" The reason is not far to seek it is that teaching has been conducted almost exclusively by specialists in *diseases* of various groups of systems and parts of the body One could scarcely expect people preoccupied with disease processes to think in terms of "health." Surely, however (and particularly in view of the altered scene resulting from the National Health Service), health should be the prime concern of family doctors and of all who have to deal with individuals as "whole beings"

The trend is for specialism to be carried into ever-narrowing fields, and it would seem that there is need for introducing at some stage of the curriculum a study of health as what might be termed a "positive factor" There is no room for complacency in regard to the health of the nation as a whole No medical man walking along the streets of any of our large towns and taking stock of the men and women between the ages of thirty and forty (when they should be at their prime) could fail to be impressed by the number who are already losing health and vigour Probably not many of these people would say that they were ill or in need of medical attention, but most of them would certainly benefit from judicious health guidance

I am not in favour of health education in bulk, since I am not sure that much of the propaganda being put across to the public is either of value or harmless Health is normally a matter for individual advice, as and when required, but in my view periodic "health" examinations carried out in each decade of life and in proper surroundings by a doctor would serve a useful
and would amply repay time and money spent
It would be wrong to suggest to the public
examinations would adequately safeguard
or even most, of the ills to which flesh is
heir, though even if limited to a physical
they would have some predictable value T
of a net to catch disease would, however, be
of their function The main purpose would be
the standard of health and when this was found
low to search, as with disease, for the cause
search would involve many factors heredity
background, personal habits and interests,
general environment, and of course the
disease processes

The value of such examinations would
limited to the individual, for the findings, if
recorded and filed, would provide extremely
information for those entrusted with the nation'
—information of no less, and probably much
value than that provided by morbidity figures.

IOMYELITIS WELSH REGIONAL BOARD AND MINISTRY OF HEALTH

—It is regretted that the British Orthopædic ation should have gained the impression as ted in Sir Reginald Watson-Jones's letter last that orthopædic surgeons are in any way excluded heir rightful place in the treatment of poliomyelitis les It is only fair to point out that the special ittee of consultants which met some time ago were g essentially with one aspect of poliomyelitis— f the respiratory complications

recommendations in the memorandum to which eginald refers, are additional to the already existing ements which are described and which make special on of the necessity for orthopædic supervision

A Trevor Jones
Senior Administrative
Medical Officer

h Regional Hospital Board
Cardiff.

CARDIOSPASM

—Your leader on this subject (Aug 15) does not on the comprehensive contributions of Irwin [6, 7] and Brown Kelly [8] These include many ations of museum specimens, all of which fail eal any organic stricture at the cardia, even where s gross œsophagectasia. The first necropsy specimen liospasm was described by Cruveilhier in 1821

y facts favour a neurogenic origin—i e., paralysis ng in particular the longitudinal musculature of sophagus ('the inhibition of contraction of the udinal coats' of Einhorn and Rolleston)

lov (1887) in his classic experiment in the dog showed ect of section of both vagi and demonstrated paralysis lower third of the œsophagus with the cardia only ll as a result of which not all the swallowed food could to the stomach but would stagnate in the lower part œsophagus; the frequent vomiting would exhaust the [9] This work of Pavlov's was carried out before the ry of X rays

erg [10] repeated Pavlov's experiment in the cat Bilateral my produced tightly constricted sphincters at the upper wer ends of the œsophagus. He demonstrated radio cally that an opaque meal introduced into the œsophagus n an animal became trapped there. If the animal was ded by the head the opaque meal was held up at the if suspended by the tail the meal was held up at the haryngeus. Paralysis of both recurrent laryngeal results in achalasia of the crico-pharyngeus.[11, 12] This is ted also in poliomyelitis

ght and Adamson [13] found that stimulation of the vagus ed relaxation of the cardia and that stimulation of the sympathetic produced contraction They also found that excision of the vagus produced the clinical and radiological picture of achalasia when the vagus and the sympathetic were excised there was no obstruction at the cardia. Brown Kelly [8] *and Rake [14] showed that there was destruction of the* nerve elements in Auerbach's plexus

Entalacão (known as tropical cardiospasm tropical dysphagia or *mal d'engasgo*) is a disease characterised by recurrent attacks of severe difficulty in swallowing It is confined solely to certain geographical regions of South America Gray [15] drew attention to this type of mega œsophagus and confirmed its peculiar geographical distribution. He attributes the cause to avitaminosis but in its distribution it acknowledges no economic barrier The cause is probably viral (akin to poliomyelitis) This produces paralysis of the longitudinal muscles of the œsophagus, the contraction of which plays an important part in the opening during deglutition, of the normally closed cardia

Much has been written on what opens the cardia (or for that matter the crico pharyngeus) but little on *how* each is opened If a thin walled rubber tube of wide calibre has in its course a constriction, closing its lumen (as a sphincter) it may be opened by stretching—i e., in the same way that the bulge of a de Pezzer catheter is flattened out by stretching Contraction of the longitudinal muscles of the œsophagus will open the cardia in the same way contraction of the oblique fibres of the constrictors opens up the crico pharyngeus by its longitudinal pull Thus paralysis of the longitudinal musculature will result in cardiospasm and a correct appellation of this condition is paralysis of the longitudinal muscles of the œsophagus.

Occasionally carcinoma of the cardiac end of the *stomach will hamper the contraction of the* œsophageal musculature and prevent the opening of the cardia. As a result from time to time there develops great dilatation of the œsophagus with vigorous peristalsis visible on screening Radiologically this simulates cardiospasm [16] The dilatation passes off but returns at intervals This intermittent cardiospasm may be for many months the first and only indication of the presence of cancer of the cardiac end of the stomach Ogilvie [17] and Park [18] have noted this association

London, W 1 N Asherson

Public Health

Pneumoconiosis

The National Coal Board and the National Union of Mineworkers have made plans for a survey of pneumoconiosis in British coalfields.[19] One of the aims of the survey which will be conducted in collaboration with the Medical Research Council will be to discover the safe limit of dustiness in which miners can work without danger to their health A mobile unit with X ray equipment will visit 21 pits throughout the country and it is hoped that every person employed in these mines will be examined The 24 pits have been selected as representative of the various conditions found in British mines. The mobile unit working from Edinburgh will make a start soon and another from Cardiff will do so later

Poliomyelitis

Poliomyelitis notifications (uncorrected) in England and Wales during the week ended Oct. 3 (39th week of *the year) were (previous week in parentheses) : paralytic,* 79 (119); non paralytic 78 (99), total 157 (218).

The reduction in notifications of 40 paralytic and 21 non paralytic cases is satisfactory and there is no doubt that the drop to the winter levels of the disease is under way

Obituary

EDMUND BRITTEN JONES

Kt., M A Oxfd, M B Adelaide, F R C P, F R A C P

Sir Edmund Britten Jones, who died on Sept 30 at the age of 64, was one of Australia's leading physicians Educated in Adelaide, he graduated in 1910 and was selected as South Australian Rhodes scholar for 1912 During the first world war he served with the Australian army medical service in India, and on returning to South Australia settled in suburban general practice for a few years In 1926 he came to England and obtained the M R C P, and when he went back to Adelaide he entered consultant practice He was elected to the staff of the Adelaide Children's Hospital, but by a combination of circumstances he was never appointed to the staff of the Royal Adelaide Hospital, and he was thus one of the relatively few consultants who have attained eminence without being attached to a general hospital After a period as honorary medical secretary, he was elected president of the South Australian branch of the British Medical Association for 1933–34 At the outbreak of the late war he at once joined the army, and served in the Middle East in command of the medical division of the 2/2nd Australian General Hospital He was elected F R C P in 1942, and in the same year returned to civilian practice where he worked extremely hard and found that his services were greatly sought after on committees and boards In 1944 he was elected to the council of the University of Adelaide and to the council of the Royal Australasian College of Physicians, of which he later became a vice president He served on the Medical Board of South Australia for several years, and was elected its president in 1950 He was knighted last New Year

G W P writes "My memory of Adelaide, which I visited as Sims professor in 1949, is of a city more English than the English In its wide streets, spacious squares, and leafy parks life pursued an even, unhurried pace In its Adelaide club lingered the manners and the courtesy of an age now passed in this country In this society the medical profession holds an honoured place, and among its leaders was Teddy Britten Jones, who in many ways typified the society in which he lived Burly of figure, eager of temperament, kind, gentle, and wise, he was a man to whom it was natural to bring troubles or problems of any kind, sure of understanding and sound counsel"

Sir Edmund is survived by a widow, a son who is a doctor, and two daughters

LEWIS GLADSTONE GLOVER

M.A, M D Camb

Dr Glover died on Sept 25 in his 86th year He had been one of the most respected practitioners in Hampstead, and, in addition to his professional duties, he had taken a considerable part in public affairs

Lewis Glover was the son of Sir John Glover, a shipowner He was educated at Highgate School and Cambridge University, where he gained a first in the natural sciences tripos He received his medical training at St Bartholomew's Hospital, qualifying in 1892 After holding house posts at the Royal Hospital for Diseases of the Chest, City Road, the Victoria Hospital for Children, Chelsea, and St Bartholomew's Hospital, he studied for a few months in Vienna He then settled down in general practice in Hampstead, at that time a rapidly growing suburb The Hampstead General Hospital was staffed by general practitioners, and Glover served on the staff with acceptance, but he withdrew in 1907 when the whole staff became of consultant status After thirty years of general practice, of which he was one of the best exponents, he retired, not to rest, but to take a more active part in his other interests

He was for fifty years a faithful member of the British Medical Association, being at one time president of the Hampstead division, at another vice-president and treasurer of the Metropolitan Counties branch, and for the years 1934–38 a member of the council of the association He devoted much time to local politics, and he was mayor of Hampstead from 1936 to 1938

He was a man with deep religious convictions, and t[illegible]rk which was probably nearest his heart was the help he gave to the Royal Medical B on the committee of which he served for over years From 1932 to 1944 he acted as treasu Fund, and until comparatively recently he attend the committee meetings He was also of St Bartholomew's Hospital In spite of deafness and the stress of a surgical operatio tinued to interest himself in these benevolent until he had entered his ninth decade

Dr Glover is survived by his wife and a daughter

FLORENCE RENA SABIN

M D

Florence Sabin died at her home in Denver at the age of 81 She was the first woman to from Johns Hopkins University, the first to teach the first woman member of the Rockefeller Inst the first woman member of the National Sciences She will always be remembered for her experimental and histological studies of the dev of the cells of the blood and of the reaction of t of the body to the tubercle bacillus Techniq she devised—particularly that of studying livi under suitable conditions of temperature and are in use all over the world today for a purposes The beautifully illustrated series of graphs produced by her and her collaborators Rockefeller Institute will be an enduring Though her conclusions on the origin of the red cell—that most controversial of all problems in tology—may not now be generally accepted, the her work gave to contemporary hæmatol immense She preceded Minot and Castle in h mental *approach to problems* that had hither attacked at a descriptive level

In the late '20s callers at her laboratory at feller Institute were welcomed by a kindly and comfortable-looking with greying hair and eyes, obviously working at the bench with her tors The shy young visitor was taken in, shown what was then the exciting "hot box" and made to feel a colleague—something that much in the early stages of research Simon called Florence Sabin "the greatest living scientist and one of the foremost scientists of a Prophecy is rash, but she certainly had a lively on the early stages of experimental cellular patho

EDWIN JOSEPH COHN

M D, Ph D, S D

Prof Edwin Cohn, whose death in Boston at of 60 was recorded in our last issue, was a d figure in American medical science Educated Amherst and later in postgraduate schools in and New York, he came under the influence of L J Henderson, then professor of biological c at Harvard, whose staff he joined in 1917 Henderson's stimulus, he began the study of the chemistry of the proteins which formed th interest of his subsequent scientific career His and personality soon impressed themselves on h leagues, and within a few years Cohn was vir control of an active team engaged in fund investigations on the solubilities and characte some important animal and plant proteins. much of this work was an extension of the Sörensen in Denmark and Hardy in this count both of whom he had worked—but later he deve along more original lines by applying Debye's on ionic behaviour to proteins and peptides.

At the outbreak of the second world war, Cohn recognised the practical significance of the earlie of his laboratory, and at once turned it to accoun development of processes suited to the la fractionation of the proteins of the plasma. through his projected programme of expansion, he and gained the support of the National Research and the American Red Cross The purified produced under his direction soon found wide ap in medicine, surgery, and the prophylaxis and of some infectious diseases Throughout this ver period, however, Cohn never lost sight of the th ations of the flood of practical studies that red from his department.

ediately the war had finished he started to re-plan oratory so that it might return to more funda considerations of protein structure This reorgan on more academic lines in which he was greatly by Dr John Edsall culminated in 1950 in the shment of the University Laboratory of Physical try Related to Medicine and Public Health ; as its director, was given the title of "university or" Chairs bearing this title had been created at d in 1936 for men of distinction not definitely d to any particular department and his appoint o one of these few and select professorships gave very special pleasure Moreover it was a notable stration of the wisdom of President Conant and lows of Harvard in emphasising once again the art that the fundamental sciences have to play in ancement of medicine

In Cohn stimulated and moulded a large number able young colleagues who came to his laboratory ly from America but from all parts of the world d an aversion to empiricism and sought always et his work by *the application of fundamental les.* It is too soon to judge his place in the develop f protein chemistry but it is undeniable that the f his laboratory and his ideas have given a great s to both theoretical and practical research in this of biochemistry A man of his vigorous personality bly provoked controversies, and their repercussions d as the circle of his war time activities enlarged ese will not dim the happy memories of those who with him—of the regular Monday lunches ulnars, and the Christmas parties where all were *air their views without reserve*

cent years Cohn received many tributes from his ountry and from abroad Numerous honorary were conferred upon him by American and Euro niversities, and he was widely recognised by scienti medical societies both for his fundamental chemical eries and for their ramifying applications in blood sion and immunology The contributions made by artment at Harvard will long remain as testimony to ability as a leader of a team of able investigators the foresight of that great medical school in ing studies in one of the most fundamental ns in biochemistry

WEN MACLEAN, of Cardiff, formerly president of yal College of Obstetricians and Gynæcologists, Oct. 13 at the age of 87

BROWNLIE J M., L.R.C.P E.: orthopædic registrar Norfolk and Norwich Hospital

CARTER, LEONARD M.B. Lond., M.R.C.P senior registrar in chest medicine Cambridge Chest Clinic

GUHA D D M.B. Calcutta surgical registrar West Norfolk and King's Lynn Hospital.

HOOPER E, R. S M B. Lond., D.A anæsthetic registrar Norfolk and Norwich Hospital

Amended notice

Notes and News

INVESTIGATIONS AT THE COLLEGE OF SURGEONS

ON Oct 7 the monthly dinner of the Royal College of Surgeons was followed by a demonstration of some of the work in progress at the college and at the Buckston Browne Research Farm at Downe in Kent

The respiratory and circulatory effects of reducing the body temperature of animals to various levels are being studied by H C Churchill Davidson, D Melrose, I K McMillan, and R Lynn, with a view to the safer use of hypothermia in surgery The blood flow in the limbs in poliomyelitis was demonstrated by A McPherson, and donor circulation experiments by A Andreasen In relation to the treatment of intestinal atresia in infants, H N Nixon is analysing the behaviour of the rabbit intestine joined by various types of anastomosis W J Dempster has continued his study of the homotransplanted kidney, and A E Kark was able to illustrate how, when the antrum is separated from the stomach and implanted in the colon, the flow of gastric juice from the remainder of the stomach can be grossly increased by stimulation of the separated antrum—e g, by its distension or by obstruction to the outflow of its contents B D Wyke, in a demonstration of cerebral localisation, was able to show, among other things, the increasing precision of methods of localising small lesions responsible for epileptic fits B E Greenfield displayed a portable electromyograph

The department of pathology had exhibits of heterologous transplantation of human tumours into mouse brain (George Lumb), the effect of androgen on hormone sensitive tumour (J Stretton-Young), cells in pleural and ascitic exudates (W Jayne), and changes in prostatic cancer after adrenalectomy (L Franks)

The demonstrations of the department of anatomy, by their diversity and close relation to function, bore witness once again to the change that has come over anatomy in the past twenty years—not least because of the collaboration of anatomists with surgical biologists such as V E Negus, who displayed the air conditioning mechanism of the nose D Tompsett showed the results of some elegant museum techniques, and Prof G Causey with H J Hoffmann showed a new model of electron microscope in action and some fascinating photographs obtained with it, using "ultra thin" sections (especially of nerves) prepared by methods which were also demonstrated Professor Causey and F Stansfield are examining the effect of vascularity on nerve grafting, and Simon Iversen is using a prototype interference microscope for the measurement of tissue density Miss J Dobson showed additions to the Hunterian Collection, Prof Kenelm Digby an experimental method of studying the ingestion of bacteria and dyes, and Professor Causey and R Sprinz a study of the effects of temporo mandibular meniscectomy

At the dinner Sir Cecil Wakeley, the president, drew attention to a portrait of Sir Henry Newland, of Adelaide, which has been brought to England by Mr A H Lendon and is to hang in the great hall when this is completed The portrait is a copy of one, by Andrew Meldrum, in the Royal Australasian College of Surgeons and was painted during his presidency of that college some ten years ago Sir Henry is shortly to hold his 80th birthday, said Mr Lendon, and one of his cherished memories is that he represented Australian surgeons at the centenary of the English college in 1900 and again at its 150th anniversary in 1950 Sir Cecil, describing Newland as one who has kept up with surgery in every part of the world, went on to speak with pleasure and pride of the decision of the American College of Surgeons to pay a visit to London "to see what we are doing"

THE MEDICAL SCHOOLS AND THE N.H S

THE aim of the undergraduate teacher, Mr IAIN MACLEOD lately affirmed, is to produce "an educated person grounded in principle and method, able to see what the whole of medicine stands for" Mr Macleod was speaking at the opening of the new session at King's College Hospital Medical School on Oct 2, and he went on to say that though as Minister of Health he was not concerned with the contents of the medical curriculum nor with the techniques of medical education, he was concerned with the end product, for he was by far the largest employer of those who emerged. Before 1948 most medical schools were under the ultimate control of the managing body of the hospital with which they were associated Today, he pointed out, medical schools were within the university sphere, and, in accordance sound principle, that the State does not university education, Exchequer assistance was the University Grants Committee, with whom the deal direct Many people felt—and he merely as a fact without coming down on either side— of the hospital service would be happier if to that method of financing the hospitals, by block grant, were instituted, and that was one he had asked Mr Guillebaud's committee to matter of urgency

SURGERIES AND WAITING ROOMS

UNDER his terms of service a general pract required to provide proper and sufficient surgery room accommodation for his patients, having regard circumstances of his practice" In a letter which been sent to every G P in the National Health Dr A Talbot Rogers, chairman of the general medical committee of the B M A, says that his committee every G P will do his utmost to provide the highest standard of surgery and waiting room accom Dr Talbot Rogers points out that recent question ment have made it clear that attention is likely to be upon isolated cases where the standard of su falls short of what is desirable, and the committee to forestall any criticism which might arise

The letter sets out the reasons which have committee to invite doctors to review the accom in their practice premises building restrictions less formidable, the widespread establishment of centres no longer seems likely in the immediate a result of the Danckwerts award, doctors may feel position to embark upon expenditure of this kind, practice expenses ratio established by the award substantial element in respect of the cost of surgery premises, so that a doctor who continues to premises of a substantially lower standard than the colleagues derives an unfair financial advantage

The committee thinks that it would be neither nor desirable to try to lay down any minimum it believes that any necessary improvements spontaneously from a wish by the doctors concerned that their premises are compatible with the of general practice in the National Health Service

DEVELOPMENTS IN RADIOTHERAPY

A NEW building which houses an 8 million vol accelerator and a 45 inch cyclotron has been the Medical Research Council at Hammersmith London. The central portion of the building is clinical rooms for patients and research laboratories

The linear accelerator, which is the first mach kind to be built for X ray therapy, has been de the Atomic Energy Research Establishment, the therapeutic Research Unit of the Medical Research and Metropolitan Vickers Electrical Company consists of a specially designed straight copper tube in length, along which a beam of electrons is acce very high frequency radio waves The electron be a gold target and X rays are produced These highly penetrating since they are generated by with an equivalent voltage of 8 million volts. In tional deep X ray therapy the voltage is 200 a few X ray therapy units in this country use 1 volts 2 million volts is also the effective voltage recently introduced cobalt 60 teletherapy unit The is positioned in the X ray beam by moving the treatment room up and down, and by using designed moving couch The three movements of beam, the floor, and the couch can be automatically by electronic equipment The high intensity of shortens the time of each treatment to about two and thus skin reactions do not develop Exten principles used in the 8 million volt linear accel made possible the design of a very compact machine suitable for use in routine radiotherapy ments, and the Ministry of Health has ordered machines for various hospitals

The 45 inch cyclotron is still under constru will produce an intense beam of high speed neu machine will be used for investigations into th *s on living and inert matter and an attempt will* le to determine whether neutrons are of value in the nt of malignant disease It will also be used for the ion of isotopes with a very short half life

NEW MEDICAL AUXILIARIES

Board of Registration of Medical Auxiliaries have ed the Association of Operating Theatre Technicians ognised qualifying body in medical auxiliary work Its is 23 Salmons Road Lower Edmonton, London N 9 ter of such technicians will be prepared and published course The association have recently inaugurated a urnal *Technic*, edited by Mr Eric Burton from St s Hospital, S W 1

TRIBUTE TO A PÆDIATRICIAN

Harold Waller has recently retired from the post of ician to the British Hospital for Mothers and Babies ich London S E 18, and a fund is being raised to morate his work since 1913 particularly on the problems ation on which his teaching has been adopted in ospitals both in this country and overseas Dr Waller g recognised that for some mothers a lying in period ays may be too short for the secure establishment of eeding and accommodation is needed at the hospital h a mother and her baby could return temporarily if ies arise. The purpose of the fund is to build a unit at the hospital where he worked for so many to accommodate one or two nursing mothers for short —not necessarily mothers with babies born at the l itself At least £2000 is required and contributions gratefully received if sent to the Dr Waller Fund at pital

THE W V.S IN ACTION

the sea broke through all along the East Coast on ht of Jan 31 this year from County Durham to Essex rs of the Women s Voluntary Services were among t on the scene—usually carrying urns of hot tea Nine later they are still on the scene helping people to their gardens ravaged by the flood waters. They have interval by feeding warming, clothing, and rehousing The report of their work (now published by Women s ary Services for Civil Defence 41 Tothill Street , S W 1) is brief modest and factual but the informal s that accompany it show clearly the kindness, resource and good humour that called forth the remark of lady at Lowestoft: I bin in three floods Miss, but he first one I've enjoyed

LAMBDA WAVES

a meeting of the Electroencephalographic Society 3 papers were read on the electro encephalogram early stages of sleep Dr W Cobb described a new nenon observed in the human electroretinogram under tensity flashes, and Dr M Roth gave further evidence existence of "lambda waves in the E.E.G., first ed by Dr C C Evans. These waves arise from random als occurring in the visual cortex and are often rved in E.E.G records owing to their low amplitude masking effect of background activity In 27 out of ects tested Dr Roth showed these waves in the ordinary They appear to be augmented by a short period of stimulation and are well brought out by scanning a ed or printed card The phenomenon is present anesthesia or normal sleep Summaries of the read can be obtained from the hon secretary Dr D A Maudsley Hospital S E.5

Royal College of Surgeons of England

At the meeting of the council on Oct 8 with Sir Cecil Wakeley president in the chair Sir James Learmonth was appointed the Sir Arthur Sims Commonwealth travelling professor for 1954 It was reported that Sir Cecil Wakeley had been appointed the Hunterian orator for 1955

Dr E Rohan Williams was admitted as the coöpted member of the council representing radiology Mr J H Doggart Mr R J Cann and Mr A. H Lendon were admitted to the court of examiners

The Ophthalmological Research Unit which has been in existence for ten years under the direction of Prof Arnold Sorsby was admitted to the status of a department of the college

The Sir Gilbert Blane Naval medal was presented to *Surgeon Captain J G Holmes* *Dr R Wyburn Mason* was awarded a Prophit research studentship The Handcock prize was presented to Mr J J Jones Mr C Ross was admitted as a Macloghlin scholar

The council approved the institution of a Mitchiner medal to be awarded annually in memory of the late Major-General Philip Mitchiner for outstanding services to military medicine by an officer of the Army Medical Service or R A.M C A similar medal presented by Sir Stanford Cade for award to a medical officer of the Royal Air Force was instituted in memory of the late Lady Cade

Diplomas of membership were granted to F J Morley and S. C C Scott The following diplomas were granted jointly with the Royal College of Physicians, to the following candidates

Faculty of Dental Surgery—At a meeting on Oct 9 the Board of Faculty of Dental Surgery elected Prof F C Wilkinson dean and Prof H H Stones vice dean for the ensuing year

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting on Oct 5 with Dr Andrew Allison the president in the chair Tavi Anjaneyulu Naidu was admitted a fellow of faculty *qua* physician.

Ciba Foundation

Prof A von Muralt (University of Berne) will deliver a foundation lecture on Thursday Oct 29 at 1 Wimpole Street London W 1 at 5 P.M He will speak on Neuro physiology—Old and New Facts and Theories

Immunisation in Young Children

A conference on this subject will be held at the Highgate wing of Whittington Hospital Dartmouth Park Hill London N 19 on Saturday Oct 31 at 2.30 P M Papers will be read by Dr W C Cockburn Dr S King and Dr T M Pollock Tickets may be had from the pediatric department of the hospital

King s College Hospital Dinner

The annual dinner of King s College Hospital Medical School held in London on Oct 3 with Mr V E. Negus in the chair was attended by 145 past and present students and guests Mr W I Daggett proposed The Chairman, and Mr Negus proposed The Medical School. On this domestic occasion their speeches were informal but gave none th less pleasure

International Congress of Industrial Medicine

This will be held at Naples from Sept 13 to 19, 1954 The hon secretary of the British members is Dr P Pringle, British Electricity House, Winsley Street, London, W 1

West London Medico-Chirurgical Society

At a meeting to be held at the South Kensington Hotel, 41, Queen's Gate Terrace, S W 7, at 8 30 P M, on Thursday, Oct 29, Mr C Hamblen Thomas will deliver a presidential address entitled Featuring the Nose

Society of Public Analysts and other Analytical Chemists

A meeting of this society will be held at 5 P M on Oct 23, at Southampton University, when Mr F H Pollard, PH D, Mr Roy Markham, PH D and Dr A L Latner will speak on Paper Electrophoresis

University College Hospital

The annual dinner of past and present students of the medical school, will be held at the Savoy Hotel, Strand, London, W C 2, on Friday, Oct 30, at 8 P M Dr Kenneth Stokes will be in the chair Tickets (£1 7*s* 6*d*) may be had from the dinner secretary, University College Hospital Medical School, University Street, W C 1

British Occupational Hygiene Society

The first conference of this society will be held on Monday, Nov 2, at 11 A.M, at the London School of Hygiene and Tropical Medicine, Keppel Street, W C 1 The conference, which is open to non members of the society, is designed to provide a common forum for the many professions—medical and non medical—concerned with occupational hygiene Further particulars may be had from Mr P C G Isaac, the hon secretary of the society, Public Health Engineering Laboratory, King's College, Newcastle upon Tyne

London Hospital Dinner

Mr George Neligan, presiding at the old students dinner on Oct 8, began by speaking of former members of the staff who had died during the year, A B Roxburgh, R J Probyn Williams, Charles Goulden, and G E Vilvandré He welcomed as new members Dr J S Pegum (dermatology) and Dr S L Last (electro-encephalography) By retirement the hospital had lost Dr W J O'Donovan ("who has cured your scabies for so many years") and the medical college its dean, Dr A E Clark Kennedy As dean for 18 years, and previously as subdean for 5 or 6, Clark Kennedy had "done his damnedest" and had shown himself always a real Londoner happily he was remaining at the hospital disguised as a physician Though the college and hospital now had separate charters and the college belonged to the university, their separation was merely on paper they worked together just as before Dr Clark Kennedy, responding, said that any limited success he had achieved in the medical college was due, first, to having a permanent alibi ("when asked to do anything in London I have had too much to do in Cambridge" and vice versa), and secondly to having people to do all his work for him He had been lucky in inheriting Mr E J Burden and the late H A Osman, and wise in choosing Mr H P Laird as secretary and Dr John Ellis as subdean The college had been most fortunate in its friends, "and in memory one among them will always outstand—our chairman" Three unsolved problems he must hand to his successor First, the medical college had grown, like other institutions, a bit too big, secondly, in view of the changing nature of the hospital's clinical material it might have to use other hospitals for teaching, and, thirdly, he was convinced that the student ought to be introduced to clinical medicine much earlier in his training Dr A G Maitland-Jones, proposing The Chairman, claimed to have seen more of him than any living man for he had assisted the late James Sherren to perform a laparotomy upon him —and those who remembered the extent of the late James Sherren's incisions would agree The London Hospital and its students had never had a better friend than George Neligan His generosity in time and money had never been equalled, and he had played a big part in carrying the hospital through the war In 41 years of friendship Dr Maitland-Jones had yet to hear him say an ill word of any man in all these years his attitude had been "with malice toward none and charity toward all"

Those who attended the dinner will long remember the ovation given to their chairman when he first rose to speak

London Medical Exhibition

Lord Horder is to open this exhibition at 11.3 Monday, Nov 16 The exhibition, in the new Royal Horticultural Society, Greycoat Street, continue until Nov 20, opening on the last 11 A M and remaining open each day until 6.30 P.M.

Competition for Medical Films

The *Presse Médicale* is again offering a prize francs and other awards for the best medical films submitted by amateurs

The films (16 mm) may not be subsidised by a laboratory or firm Further particulars may be had secretariat of the journal, 120, Boulevard Saint-Films should reach the secretariat not later than March

Nuffield Inquiry into the Causes of Crime

The Nuffield Foundation has invited Lord undertake a critical appraisal of current views—by actions and in writings—of the causes of crime. be assisted by a small group of assessors, Dr Desmond Curran, psychiatrist to St George's Hosp Dr T C N Gibbens, lecturer in forensic psych Institute of Psychiatry in the University of London

Medical Statistics

The study circle on medical statistics of the Royal Society will meet on Tuesday, Oct 27, at 6 P.M. at minster Medical School, Horseferry Road, London, report on Measures of Morbidity in Public Heal Statistical Aspects of Disease Classification F lars may be had from Mr M P Curwen, St. Barth Hospital, E C 1

British Postgraduate Travelling Fellowships

The British Postgraduate Medical Federation applications from doctors and dentists for these fe which have been set up to enable graduates who are as specialists in one of the preclinical or clinical medicine, surgery, or dentistry, to obtain experi methods of practice, education, and research at or other centres in the United Kingdom and abroad. particulars will be found in our advertisement columns

Synthesis of Oxytocin

Prof Vincent du Vigneaud, who holds the chair chemistry at Cornell University Medical College, is reported to have announced in the *Journal of the Chemical Society* the synthesis by himself and his of oxytocin (*New York Times*, Oct 7) The same the society's journal contains an article from Vigneaud's department giving a proposed chemical for vasopressin

Society of Chemical Industry

This society's food group (nutrition panel) is to series of meetings with the general title Reappraisals At the first meeting, to be held in of the Chemical Society, Burlington House, London, W 1, on Wednesday, Oct 28, at 6 30 P.M., Bender, PH D, will speak on Proteins Later meet deal with Calories and Basal Metabolism (Dec. 9) and (Jan 27)

CHILDREN IN HOSPITAL

PREPARATION FOR OPERATION

RONALD MAC KEITH
D.M Oxfd F.R.C.P
STANT PHYSICIAN CHILDREN'S DEPARTMENT GUY'S HOSPITAL, LONDON

DREN'S reactions to operations vary Many
lly if over five years old seem quickly to forget the
hospital and its necessary unpleasantnesses A
m to behave better afterwards, as if surviving an
nce they thought would be bad has given them
onfidence in life and in themselves. A considerable
r, chiefly among those under five show changes in
our for a shorter or longer period after The
s are chiefly fears—of the dark of being alone in
ratory, *of being alone—and regression to more*
behaviour such as wetting by day or night
g to be fed or negativism Fears of doctors,
and strange men are frequent fear of the dark
fear of separation from the mother which may
ow itself as insomnia In some children a later
hospital or doctor reveals fears that were not
at home

tivistic reactions—disobedience, tantrums spiteful
fiant behaviour—occur chiefly in children of five
r older and can greatly try parents on the child's
home Increased dependency is another symptom
n be wearing to a busy mother It is so common
e almost a normal sequel.

nan (1949) regards psychological trauma after
ctomy as a *complication as deserving of the*
s thought as is postoperative bleeding or infection
aration is often the occasion of a child's first
ion from home, or if he has been away before it
a happy visit without attendant anxiety It is
for people who work in a hospital to appreciate
iety that the special event of going into hospital
for any but the most self-confident. Strange
trange food, a strange routine an unfamiliar bed—
e ceiling is unusually distant Langford (1937)
g 20 children with anxiety states found that in 6
rder was related to tonsillectomy for which the
had, as a rule been poorly prepared Of another
f 124 children who had had operations often a
ctomy 25 had emotional upsets for longer or
time (Levy 1945) The symptoms were most
n at the ages of one and two probably because the
were then more dependent on their mothers did
derstand what was happening and could not get
heir anxiety in words or play Night terrors were
en in these younger children for months.

evy's series, in 13 of the 25 children who were
othing beforehand had suggested that this would
It is *true that a child who* has shown lack of
fidence is more likely to be upset but one cannot
that a happy confident child of two three, or
ll necessarily show no disturbances Sometimes
first operation has produced little disturbance a
will disclose that the first left after effects.

hildren who come into hospital for operations
nce some degree of anxiety The film *A Two*

on This film opens one's eyes to the quiet
iness that a young child in hospital may suffer
f the day almost unnoticed by the nurses and
We do not want to see the grief and we see
good quiet child If a child is crying we may
this crying to the crying of a small child who is
hungry or has fallen We tend to dismiss all crying as common and unimportant

Three Anxieties

The three main anxieties which centre round an admission to hospital for operation are the separation from home the anæsthesia, and the operation.

SEPARATION

Some children under four feel so lonely and deserted that they do not seem to notice the operation much This is especially true of children who have to stay longer than they expected and of children who are not too trusting of their parents statements (Jessner and Kaplan 1949) Older children can understand the separation as an episode the younger child has a more intense attachment to his mother and may react severely, *and even if he settles down he may reveal that he felt* intensely by his behaviour on returning home Bowlby (1951) has shown that mental health and ability to get on with people in later life may depend on a warm and continuous relationship with a mother (or permanent mother-substitute) Severe deprivation can seriously disturb personality It seems probable that shorter deprivations may lead to slighter but still handicapping disorders such as diminished self-confidence Even if it did not sadness in small children is something to be avoided as far as is in our power The child reasons and if he is anxious he may conclude that his mother left him because she did not love him To an anxious person in a strange world the most fantastic idea may seem reality

ANÆSTHESIA

The fear of losing control as they feel themselves slipping away under the anæsthetic is common in older children (of say six to twelve years) given ether for tonsillectomy (Jessner and Kaplan 1949) Children sometimes have unexpressed foolish fears of what will be done while they are under the anæsthetic sometimes from what thoughtless children or grown ups have said A kindly nurse said what lovely eyes you have I wish you'd let them change them for mine while you're under the ether Some small children genuinely fear they may die a little girl's first statement on coming round was: I didn't die

OPERATION

Children's ideas about operations and even about minor incidents of hospital routine, can be surprising Some children will say they want their tonsils done so that they can have ice-cream like their brother had after tonsillectomy Some imagine they are to have major procedures that have happened to their parents—thyroidectomy gastrectomy—details of which have been overheard at home

Sometimes needles rectal temperature-taking hospital clothes, or being put into a cot are disturbing children sometimes interpret them as punishments for real or imagined naughtiness

Some have remarkable fantasies as to what happens in so-called minor operations The child newly admitted for tonsillectomy may silently assume that this is what has been done to the child in the next bed with his eyes *bandaged Incidentally quite a few children wonder* what becomes of the appendix or tonsils removed and rather resent that they are thrown away as rubbish

According to Jessner and Kaplan (1949) the children who cope best with hospitalisation are the confident children who can transfer positive affection from the mother to the nurse those who interact with other children those who are interested in games and toys those who can express themselves *indirectly* by crying anger or naughtiness, with only moderate limitation or self control "The child should be given the opportunity to express as much of his feelings as his own standards allow him to One should not interfere with this capacity for self-expression by an effort to coach the child to be good and brave"

It seems important to let the child set his own standard of self-control, reassuring him where possible about his fears but accepting these and his tears with sympathy, remembering the therapeutic benefit of a good cry for grief-stricken adults, and remembering also that a temper tantrum is itself a frightening experience for a child, for which he needs to be comforted

Some children behave better and are happier after operation because their health is better Among older ones, a few may be better for the emotional experience Most normal children and some "insecure" children escape lasting emotional sequels Many more or less disturbed children and some normal children show evidence of anxiety after operations (Levy 1945) Some children who seem to take the experience very easily, show by behaviour long afterwards that they have suffered, asthma may date from an operation such as tonsillectomy

How the Doctor Can Help

Can I see another's woe
And not be in sorrow too ?
Can I see another's grief
And not seek for kind relief ?
Blake. Songs of Innocence.

What can we do about these possible effects and after effects of a stay in hospital ? Coleman (1949) suggests the following helpful measures

1 Give the child a forthright and honest explanation of the reasons for the operation

2 Try to avoid the element of surprise and confusion at the hospital A recognisable picture of the hospital, the operating-room, and the white-gowned nurses and doctors should be presented in advance

3 Explain that the purpose of anæsthesia is to spare the child pain during the operation. Assurance must be given that this forced sleep is temporary and will be followed by complete awakening and survival The ideal anæsthetic is one chosen for surgical efficiency and psychic consideration

4 Emphasise to the parents the need for constant reassurance and affection in the postoperative period

5 Whenever possible, the doctor personally should lead the child from the mother to the operating-room The previously established child-doctor rapport here pays dividends in the sustained security

6 Permit overt expression of postoperative hostility, rather than suppress it The psychic damage of such suppressions is fraught with subsequent danger

Levy (1945) and Jessner and Kaplan (1949) suggest postponing operations, if possible, until the child is at least four, when it is less disturbing for him to be separated from his mother and when he can understand something of the meaning of the operation The disturbance is perhaps least between the ages of five and ten years Operations should also be postponed if possible in children who are unusually timorous or dependent on their mothers If operation is unavoidable special care should be taken before, during, and after hospitalisation Operations are also best avoided at a short interval after a previous stay in hospital or other separation, after a family bereavement, or when the mother is having another baby, or even while the family is moving house

BEFORE THE OPERATION

It is clear from *A Two-year old Goes to Hospital* that a familiar toy, slippers, clothes, or other tangible tie with home can be a reassuring comfort Parents should not be to let the child bring the favourite shabby doll or toy In this film a doll and a very shabby blanket were wisely allowed to the child with about sepsis after all virulent germs are rare in households

> "One youngster in the Harriet Lane Home (the hospital at Johns Hopkins Hospital) had a pair of which he insisted on wearing in bed. They stay in bed for several days except when he allowed th take them off He wore them up to the operating only permitted them to be taken off after arrival (Trainham 1949)

The parent should indeed be specifically bring some such toy The familiar object a child because he knows himself as the owner object—and there it is beside him in his similar reasons the child should come back theatre to the same bed in the same room before, otherwise he may worry that his know where he is

In running the ward, discipline and routine adapted to the individual child's need. T punishments are out of place and a period in rarely the right time to teach better manners or to cure children of sucking their thumbs or dummies

A preoperative sedative is nearly always although some children become excited and The anæsthetist does a great deal to allay a child's especially if he knows what these fears are McDonald (1953) has described the usefulness sodium thiopentone in lessening postoperative disturbances in children

Twenty-four hours in hospital before a child to get over his first panic and to establish with his fellow patients, the nurses, and doctors. tedly this lengthens the period of separation, have recommended that operations on young should be done in the home But the possibility operative complications is a potent argument this "The solution is to bring the home hospital" (Foord, 1949)

The doctor who admits the child to hospital mindful of childhood's problems The pædiatric officer often appreciates these better than his colleague who has had no special experience in and may forget to explain things to mother and

The Mother in Hospital

The mother brings the child to hospital and hospitals gives him his bath and puts him in it is certainly possible for her to be there while gives him his bath if he is dirty she may learn standards of cleanliness Even the examination lice need not be postponed till the mother is mothers of children at local authority schools to their children's heads being inspected. bath the mother explains things to the child having told him when she will be back again, going away and goodbye With babies, not, it is ideal for the mother to come in with In New Zealand the Pickerills, for their operations, have a hospital built on the chalet principle for mothers to come in with and their babies

Daily visiting is always wise and humane If is anxious, she should be reassured by Mothers can be led to understand how their adversely affect their children In an air raid mother with her child in her arms was shelter when she realised her terror was felt child She slowed to a walk, looking up and out the "lovely aeroplanes" droning above

Sometimes parents are distressed because their cry or turn away when they come to see them.

that a child may remember in a rush how much he)een missing Anna Freud has said it is important ll children in hospital three things :

He is still very much loved
He is not being punished
He is getting better

nurses and mothers should put these things into)s to all children, however small and however happy seem It can do no harm and may give great relief ors, nurses, and parents all do well to give a child, ver small, credit for understanding—or feeling— i is said or felt.

hen it is suggested that mothers should come into ital with their children it is usually pointed out they may be *anxious and upset the child* Mothers and this would be true of some of them ; but the nent is sometimes a rationalisation of a desire to the mother out of the way This is not always ntirely unreasonable attitude for the confident ude of the regular nursing staff is helpful to a

has been suggested that mothers should accompany ren to the induction, but it may be upsetting to a to find that his mother coöperates in the " attack im. If a preoperative sedative is given it seems cessary for the mother to go to induction of a semi ious child When a child does not have a pre itive sedative, he should be carried to the anæsthetic by a familiar nurse or accompanied by the nurse porter carries him and that this nurse should stay him until he is unconscious Certainly being lled on a trolley lying flat so that one cannot see e one is going is alarming The first waking of a after operation would alarm some mothers, and child probably would not realise whether she was or not. The mother should, however visit on the ing of the day of operation The ward sister should her if the child is likely to be confused or bloody ough children in hospital are more difficult when their iers are admitted with them, the postoperative ulties are so much less that Escalona (1949) agrees it is worth while

iother suggestion for bringing the home into the ital" is to allow children to eat home-cooked food iout experience it is difficult to say whether this d be worth arranging but food prepared by his ier might mean a great deal to the child apart from 'act that children are conservative and like the sort od they are used to Some children comfort them in hospital by eating more than they do at home n a child s mind food and his mother are closely lated.

Telling the Child

ie parents have an extremely important part to in preparing the child before he goes into hospital. important that they and he both know what will en there The mother and father must know what happen in hospital so that they can answer the tions the child is certain to ask. It is a good plan he child to enact at home the admission to hospital anæsthesia, and the operation

hildren will also be helped if they know beforehand they are likely to miss their parents and may be ly A mother of two children, aged 8 and 10 years divorcing her husband. She explained the situation he little girls who remained with her throughout er the 10 year old said Mummy you told us what ld happen, but you didn t tell us how we d feel ' idred 1953) Edelston (1943) has remarked that clinical experience the determining factor (for ptoms after separation) seems to be the degree of ction or insecurity *felt by the child* "

How long beforehand should the child be told ? Some say months, some say a few days It probably should be shorter for the more timorous children Certainly the child should be told so that what happens is not all unexpected.

The parents and everyone else concerned should also know what *not* to tell children A medical student tells a child about to have a laparotomy that ' it won't hurt." Yet the child's abdomen *will* hurt after the operation A mother, as she leaves tells her child that she will be back in a minute " Another tells her child that she will be sleeping in the room below (so the poor child later went on to the balcony and screamed ' Mummy Mummy ') A little girl is told to behave—or she will be left in hospital ' an anxious boy about to go into hospital is told to stop playing with himself or the doctor will cut it off while you are under the anæsthetic "

These remarks are not made in malice even though they are untrue and wrong The parent says Oh he is too young to understand,' which is almost certainly not true or I didn t want to make him unhappy,' although in the long run the discovery of deceit is more upsetting Undermining the child's confidence in what he is told does not help the hospital staff and often a child can accept unpleasant news more easily from a parent It is fairly easy to understand a medical student with no experience of bringing up children comforting a child by misleading statements it is less easy to under stand parents doing this. Telling such palpable untruths does not make bringing up children easier and apart from that it is a poor example Anyway telling the truth is an important principle of science in general It might " ring the bells of heaven ' quite loudly if we stopped telling children this won t hurt you just before sticking a needle into them

Parents, and especially the mothers need guidance in preparing a child for the experience of being in hospital It might be useful to prepare a leaflet for them to read One thing is certain adults deceive themselves when they dismiss the facts that small children in hospital are often anxious or sad, and that such anxiety often permanently lessens the child s reserves of self-confidence They are in fact, resorting to a functional blindness by which *they spare themselves awareness of children s* suffering

This article arose from a conversation with Miss Tanner sister of the children s surgical ward at Guy s Hospital and I thank her Miss Duncombe of the children s medical ward Mrs. M Oppé and Dr P E Polani Dr D G Vulliamy Dr T E. Oppé Dr P J Lyne and Dr D M E. Allen of the department of child health, Guy s Hospital for their help

The influence of Dr H C. Cameron s example of under standing and sympathy with children will be evident and it is appropriate that Guy s was the first teaching hospital in London to have regular daily visiting of children

RADIOGRAPHY IN THE DIAGNOSIS OF HYALINE MEMBRANE

IAN DONALD
M B E , B A Cape Town, M D Lond , M.R C O G
READER, INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF LONDON
R E STEINER
M B N U I , F F R , D M R
RADIOLOGIST, HAMMERSMITH HOSPITAL, LONDON

With illustrations on plate

THE diagnosis of hyaline membrane within the lungs of infants dying in the first few days of life can only be made with certainty post mortem The association of this membrane with atelectasis is now increasingly recognised , and, since atelectasis is generally accepted as the most important single cause of death in premature infants, the clinical importance of being able to diagnose hyaline membrane during life is obvious

Claireaux (1953), in his histological examination of the lungs in 376 cases of neonatal death, found hyaline membrane in 108 (29%), of which four fifths were in premature infants and in no less than 21% of the 376 cases hyaline membrane was the only abnormality discovered

Unfortunately it is no easy matter to diagnose the cause of a baby's respiratory difficulties on clinical grounds alone At best a shrewd guess may be made that hyaline membrane may be present if a baby, within the first few hours of life, exhibits increasing dyspnœa, grunting respirations, inspiratory recession (either subcostal, intercostal, sternal, or suprasternal), the use of accessory muscles, cyanosis, poor air entry, and bouts of apnœa The diagnosis is still more likely if the baby is premature or has been delivered by cæsarean section because of maternal diabetes , but a similar clinical picture can be evoked by other conditions such as intraventricular and subdural hæmorrhage, primary atelectasis, pneumonia, œsophagotracheal fistula, diaphragmatic hernia, and pulmonary hypoplasia The ante-mortem diagnosis of hyaline membrane might be of little more than academic interest were it not for the possibility of treatment and the bad prognosis which these clinical signs often betoken

To learn how far this pathological process is reversible demands an ability to diagnose it before death, and the success of any treatment adopted can hardly be substantiated without the diagnosis, except perhaps on the quicksands of statistics, if the infants recover and do not come to necropsy

In our researches into neonatal atelectasis and its treatment it is therefore natural that we should have invoked the help of radiology

The extent to which babies in respiratory distress are not radiographed is common experience, and is possibly part of the traditional " no touch " technique Nevertheless, both in diagnosis and in assessing progress, we have found radiological investigation of considerable help when taken in conjunction with clinical examination, spirometry, and other diagnostic aids

Surprisingly little has been published in this respect Caffey (1945) noted radiological signs in the lungs of premature infants but dismissed their pathological significance An article by Donald and Lord (1953) on augmented respiration in the treatment of neonatal atelectasis was illustrated by radiographs showing radiological signs in some of their cases in which hyaline membrane was found at necropsy Two months later Meschan et al (1953) published a case of proved hyaline membrane and demonstrated radiological changes which are now familiar, but we have been unable to find a sequence of radiographs comparable to those we now reproduce

Three different stages in the evolution of membrane have been identified radiologic correlated with the clinical and necropsy findings

(1) First there appears a fine miliary mottling th the lung fields

(2) This is followed in the progressive lesion by and more coalescent type of opacity At this st bronchial tree is often clearly demarcated

(3) Finally the shadows become confluent as a lobar or lobular consolidation and collapse

The baby may die of some other lesion—e.g., an intraventricular hæmorrhage—before all three are radiologically demonstrable and unless radi are taken every few hours it is likely that the of events will not be observed

Up to date 28 newborn infants at Ham Hospital with respiratory distress have provided of radiological interest which are here described. other cases so investigated do not concern the of this paper and have been omitted The cas been divided into five groups as follows

Group I —Significant radiological signs, and membrane found at necropsy (11 cases)

Group II —Clinical signs of atelectasis, but no radi signs, and hyaline membrane not found at necropsy (

Group III —No radiological signs, but hyaline me found at necropsy (0 cases)

Group IV —Radiological and clinical signs pres child recovered , diagnosis therefore unproven (4 cas

Group V —Radiological signs present, but lesions than hyaline membrane at necropsy (5 cases)

The last group might be called the false positives

Case-records

GROUP I

(Radiological Signs Confirmed at Necrop

Case 1 —One of twins, the other being anen delivered at 32 weeks Birth weight 3 lb 8 oz. Cy grunting, and clinical signs of atelectasis at 1 hour mented respiration produced temporary improvement Died at $9^3/_4$ hours

Radiography at 3 hours showed fine mottling but n collapse (fig 1) At 8 hours radiography showed mottling, the degree of collapse was progressive and the lower lobe appeared solid (fig 2) At necropsy there almost no aerated areas of lung, and microscopy hyaline membrane Death was attributed to atelectas intraventricular hæmorrhage was a contributory facto

Case 2 —Lower segment cæsarean section at ter antepartum hæmorrhage Birth weight 6 lb 8 oz Ha well for seven hours, when cyanosis occurred and s atelectasis rapidly developed She was intubated at $9^1/_2$ and oxygen was supplied with intermittent positive Respirations were augmented from 11 hours with improvement, the endotracheal tube remaining in s for technical reasons the treatment was discontinued 6 hours and the child died at $17^1/_2$ hours.

At $9^1/_2$ hours radiography showed coarse mottlin post mortem it showed total collapse At necropsy o anterior border of the right upper lobe floated, a presence of hyaline membrane was confirmed histolo Death was attributed to secondary atelectasis

This case has previously been described with illustrations (Donald and Lord 1953, case D1)

Case 3 —Delivered at 33 weeks Birth weight 4 lb Cried at once, but respirations became irregular with and inspiratory recession Died at 7 hours. At death was attributed to atelectasis. A subdural on the right was regarded as a contributory factor pulmonary aeration was macroscopically visible, a microscopy the alveolar ducts and respiratory bron were seen to be overdistended and lined with hyaline brane The radiograph before death showed co shadows in peripheral lung fields, with sharply o bronchial tree (fig 3), and post mortem almost deflation (fig 4) in spite of attempts to reinflate after the absence of earlier films it might be difficult 3 to distinguish between primary atelectasis and ced hyaline membrane on radiological evidence , but the prominent bronchial tree is significant may suggest hyaline membrane with peripheral tasis.

se 4—Delivered at 28 weeks. Birth weight 2 lb 1 oz. netry at 2 hours showed a minute volume of 410 ml respiration. Radiography at 11 hours showed incomplete on and death occurred at 12 hours At necropsy a intraventricular hæmorrhage was found responsible for but the lungs showed only patchy aeration of the portions of both upper lobes and the right middle lobe atter alone floated Histologically many respiratory hioles and alveolar ducts were overdistended and lined aline membrane The surrounding lung was collapsed *were also signs of early pneumonia*

out the earlier spirometric record one might have in doubt whether the radiological signs were those imary atelectasis or hyaline membrane

se 5—Alleged gestation 28 weeks, probably 32 weeks. weight 4 lb 2 oz. There was sternal recession, cyanosis, grunting His condition steadily deteriorated and at the f $4^{1}/_{2}$ hours respiration was augmented, with improvein minute volume but seal leaks developed at 9 hours at $10^{1}/_{2}$ hours

diography shortly after admission at $2^{1}/_{4}$ hours showed tippling throughout the lung fields with clear definition bronchial tree and a further film at 10 hours showed ation and coarser and increased mottling At necropsy the infero anterior border of the right middle lobe was aerated, and the presence of hyaline membrane was med on microscopy Death was attributed to secondary tasis.

se 6—*Breech delivery at 26 weeks following ante*m hæmorrhage Birth weight 2 lb 8 oz. There was unced recession and grunting Became moribund at 5 and died at 8 hours. Radiography at 5 hours showed it no evidence of pulmonary inflation but the bronchial was well outlined

he absence of earlier radiography it would be ult to distinguish the radiological appearances those of primary atelectasis, apart from the possible ficance of the demarcation of the bronchial tree ecropsy death was attributed to atelectasis there little evidence of aeration, and microscopy showed ine membrane

se 7—The third of triplets delivered at the 33rd week, nother having pre-eclamptic toxæmia. Birth weight 16 oz. Initial condition good, but grunting respiration vened, with severe recession. At 7 hours respiration ugmented until technical troubles developed after three . Recession persisted, and death took place at 20 hours. diography at 6 hours and 12 hours showed coarse ling, which in the later radiograph had become more ounced The bronchial tree was well demarcated At psy both lungs were unaerated and microscopy showed sive hyaline membrane Death was attributed to ctasis.

se 8—Delivered at 34 weeks. Birth weight 4 lb 6 oz. l well at birth but became cyanosed Subcostal recession conspicuous within ten minutes. Respirations were ting Inspiration was augmented intermittently with ive pressures from the age of 35 minutes onwards with temporary improvement Repeated cyanosis was *wed by death at 9 hours.*

diography at $3^{1}/_{2}$ hours and half an hour before death ed bilateral atelectasis involving segments of upper and r lobes. The bronchial tree was well outlined and the ad radiograph showed little improvement At necropsy was only patchy aeration of the right lung (positive ure insufflation had been continued post mortem) oscopy revealed hyaline membrane Death was attributed telectasis although there was also a small intraventricular orrhage

se 9—Precipitate delivery at 29 weeks after painless partum hæmorrhage Birth weight 3 lb 13 oz Severe yxia at birth with much inspiratory recession Condition rapidly deteriorated, gastric oxygen was administered but the heart stopped after two hours. Radiography immediately after death showed total collapse of both lungs, without any evidence of aeration (fig 5) Necropsy showed gross atelectasis and on section the lungs were *found to be slightly expanded* as a result of aspiration of liquor amnii Some of the alveolar ducts showed developing hyaline membrane

This radiograph differs from that of the previous case particularly in the absence of demarcation of the bronchial tree and we are inclined to regard this picture as essentially one of primary atelectasis although hyaline membrane was found

Case 10—One of twins. Breech delivery at 27 weeks. Birth weight 2 lb 2 oz. Considerable recession, mainly subcostal, and respiration was augmented Repeated cyanosis ensued and was followed by death at $38^{1}/_{2}$ hours.

Radiography at $2^{1}/_{2}$ hours 14 hours and 10 hours showed granularity and outlining of the bronchial tree At necropsy the right lung floated as a whole but only the middle lobe was reasonably well aerated Both lobes of the left lung sank, and only the anterior border and lower tip were aerated There was a large bilateral intraventricular hæmorrhage and clot was present *in the fourth ventricle* Death was attributed to this, but the lungs on section revealed early hyaline membrane as well constituting a contributory factor

The other twin (mentioned elsewhere) showed radiologically good expansion and no hyaline membrane was found post mortem It too died of intraventricular hæmorrhage It appears that the finer the granularity the earlier is the stage of development of hyaline membrane

Case 11—Delivered at 35 weeks. Birth weight 3 lb 3 oz Baby was admitted at the age of 6 hours with pronounced inspiratory recession and grunting respiration. Condition at birth initially good During the first 30 hours respirations were intermittently augmented with temporary improvement in the child's colour but recession persisted Jaundice developed at 62 hours with hardening of the skin Death took place at 68 hours.

Radiography at 8 hours (fig 6) 11 hours 26 hours about 30 hours (fig 7) and 48 hours (fig 8) showed very fine mottling throughout both lungs with partial deflation on the left which progressed in subsequent films, but in the 48-hour film some re-expansion of the left lung had taken place and the mottling throughout had decreased, suggesting regression in the alveolar deflation At necropsy the left lung sank the right lung floated and showed partial aeration, and microscopy showed extensive hyaline membrane vascular congestion and some intrapulmonary hæmorrhage Death was due to atelectasis.

GROUP II

(Cases in which the Diagnosis of Hyaline Membrane was Considered but Excluded by the Help of X rays)

Case 12—Lower-segment cæsarean section at 37 weeks for maternal diabetes. Birth weight 8 lb. 2 oz Inspiratory recession was marked during the first 36 hours but spirometry showed improving minute volume and radiography at 30 minutes showed full expansion which was confirmed 21 hours later

In view of the well known tendency of hyaline membrane to develop after cæsarean section for maternal diabetes this information was valuable

Case 13—Breech delivery at 26 weeks. Birth weight 1 lb 11 oz. *At birth the baby was toneless and shocked* Respiration was augmented intermittently until the age of 11 hours. Condition remained satisfactory until 24 hours, when cyanosis developed Death took place suddenly at 32 hours. Radiography at 6 hours showed clear lung fields, and post mortem showed negligible pulmonary aeration and absence of bronchial tree markings At necropsy there was only slight aeration of the right middle lobe anteriorly and the anterior borders of both lower lobes. On section the lungs were found to be immature and many of the alveoli were lined by cuboidal epithelium. There was no hyaline membrane Death was due to atelectasis, which was evidently secondary but not associated with hyaline membrane.

Case 14—Abortion at 26 weeks Birth weight 1 lb 10 oz Respirations were very shallow and were augmented until at 8 hours the condition was greatly improved, and baby was transferred to an incubator

Radiography at 12 hours showed no evidence of pulmonary consolidation nor deflation Death occurred at 26 hours from intraventricular hæmorrhage The lungs showed only partial aeration (about 50%), and on microscopy atelectasis appeared almost complete except for groups of alveoli near the surface of the upper lobes. Many alveoli contained acidophil debris but without hyaline membrane

Case 15—Abortion at 27 weeks Baby cried at birth, but immediately became grey Aspirated, and respiration was augmented during first 3 hours because atelectasis was obvious Condition improved considerably, and radiography at 3 hours showed fairly good expansion and no evidence of collapse Transferred to incubator at 3 hours Died at 8 hours At necropsy the upper lobes were quite well aerated, but the lower lobes sank There was no hyaline membrane, and death was due to intraventricular hæmorrhage

Case 16—First of twins aborted at 27 weeks Birth weight 1 lb 11 oz Baby was pink at birth and cried well, and there was only slight recession.

Radiography at $4^1/_2$ hours showed good pulmonary expansion, and at 22 hours "excellent expansion" From 20 hours onwards there were increasingly frequent attacks of cyanosis, and the baby died at $38^1/_2$ hours At necropsy all the lobes floated, and on microscopy small areas of collapse were seen alternating with areas of over-distension. Hyaline membrane was absent, apart from an occasional minute fragment Death was due to intraventricular hæmorrhage

Case 17—Delivered at 32 weeks Birth weight 3 lb 12 oz Condition was good at birth, but there was subcostal inspiratory recession

Radiography on the first and second days of life showed full expansion Death took place at 46 hours Intraventricular hæmorrhage was found at necropsy, but lung expansion was very good, and there was no sign of hyaline membrane

Case 18—Second of twins. Forceps delivery at 34 weeks for maternal eclampsia at full dilatation Birth weight 3 lb 9 oz Consistently poor minute volume Respirations were augmented with some improvement

Radiography at 13 hours showed good aeration of both lungs, but death took place at 51 hours At necropsy a large tentorial tear was found. The lungs floated but were congested, and there were patchy alveolar hæmorrhages There was no hyaline membrane, but there was widespread patchy pneumonic consolidation.

Case 19—Delivered at 32 weeks Condition at birth was very good Birth weight 3 lb Spirometry at 15 minutes showed a minute volume of 333 ml with the baby quiet, and 827 ml with the baby crying At 1 hour the baby, during a burst of crying, achieved a minute volume of 1500 ml

Radiography at 1 hour 5 minutes and $4^1/_2$ hours showed good pulmonary aeration, although in the earlier stage there was some crowding of the markings at the base on both sides The signs did not resemble those we have come to associate with hyaline membrane The second radiograph showed improved expansion on the left but no change on the right The child survived

GROUP III

(Negative Radiological Signs with Hyaline Membrane found at Necropsy)

There have been no cases in this group to date

GROUP IV

(Radiological Changes Present but Infants Lived and Hyaline Membrane therefore Not Proven)

Case 20—Delivered at 32 weeks Birth weight 3 lb 8 oz Severe atelectasis, but minute volumes improved spontaneously during first two days Radiography at 2 hours showed coarse mottling, which had mostly cleared on radiography at 16 hours Radiography on the third day showed no mottling at all The baby recovered

Case 21—Rapid delivery at 28 weeks Birth weight 2 lb 15 oz Condition at birth good, but grunting and subcostal recession developed within 50 minutes.

Radiography at 1 hour showed incomplete expansion of right upper and middle lobes, with some fine mottling consistent with alveolar collapse Spirometry at 65 minutes showed a minute volume of 234 ml Respiration was augmented, and minute volume rose to over 600 ml. 50 minutes Further radiography at 7 hours showed expansion in the right upper and middle lobes. The since done well.

Case 22—Delivered at 33 weeks Birth weight Colour bad and atelectasis gross Respiration and minute volume slowly improved from 242 ml at 11 hours, with quiet respiration Child has although some degree of sternal recession persisted 48 hours

Radiography at $7^3/_4$ hours and $10^1/_2$ hours and outlining of the bronchial tree

Case 23—Delivered at 32 weeks after hæmorrhage Birth weight 3 lb 7 oz were grunting, and there was subcostal recession sisted for 2 days Minute volume of 507 ml. with the child quiet

Radiography at $1^1/_2$ hours (fig 9), 8 hours, and day, 4th day (fig 10), and 19th day (fig 11) mottling throughout at first which gave place to variety which in patches appeared somewhat confluent radiograph on the 19th day showed these changes disappeared The child has continued to do well.

GROUP V

(X-ray Changes Indicating Pulmonary Hyaline Membrane not Confirmed at N

Case 24—Delivered at 34 weeks Birth weight Initial condition good, but clinical signs of oped Minute volume 220 ml at 4 hours but 1100 ml after augmented respiration For the treatment was abandoned after two hours. attacks of cyanosis Death took place at 27 hours.

Radiographs taken at 4 hours, 8 hours, and death (fig 12), showed a very fine stippling and atelectasis These appearances became more each of the successive films At necropsy there intracranial hæmorrhage Pulmonary aeration appeared good Histology showed numerous the bronchioles, but there was no hyaline membrane. if the baby had lived longer, the recognised pattern of membrane might have developed Other illustrations case have been published (Donald and Lord 1953,

Case 25—Delivered at 26–28 weeks Birth weight Temperature on admission was 88°F, and there recession on inspiration Baby died suddenly, warning attacks of cyanosis, at 26 hours

Radiography at 7 hours showed very poor 20 hours some improvement, but there was

tling throughout both lung fields and the bronchial tree not outlined as described in earlier cases. At necropsy nonary expansion was moderate and both lungs floated roscopy revealed no hyaline membrane Death was ibuted to pneumonic consolidation.

Vhen hyaline membrane is present collapse seems to gress from alveolar to lobar In hyaline membrane ase we have not so far seen this progression reversed reas in this instance pneumonia or primary atelectasis gressed from lobar to alveolar collapse and consolida The radiological sequence therefore appears to be ortant in the differentiation of the two conditions

ase 26.—Forceps delivery at 34 weeks for maternal mpsia at full dilatation First of twins Birth weight b 3 oz. Shocked at birth Respirations shallow with equent gasps Augmented respiration applied. Died at iours.

adiography immediately after death showed very poor ation on both sides No mottling was visible nor was the nchial tree outlined and we are inclined to regard this as ase of primary atelectasis. At necropsy all the lobes ted. Microscopy revealed overdistended alveolar ducts widespread areas of atelectasis but no hyaline mem ne Death was due to a large intraventricular hæmorrhage

ase 27.—Rapid delivery after antepartum hæmorrhage at weeks. Birth weight 2 lb 9 oz Recession developed and nosis deepened within an hour whereupon respiration was mented intermittently

adiography at 2 hours showed fairly good expansion of right lung but the left lower lobe was somewhat collapsed o mottling was visible throughout the lung fields. Although signs of recession had largely disappeared by $5^3/_4$ hours, ther radiography at this time showed the mottling to sist but the left lower lobe appeared better expanded diography at 20 hours and 48 hours showed further provement Nevertheless the child died at $4^1/_2$ days and necropsy the immediate cause of death was not determin o All lobes floated but there was some patchy emphysema hyaline membrane

this case either the radiographs gave a false positive ult or hyaline membrane was in fact present but olved before death

ase 28.—Delivered at 32 weeks Birth weight 2 lb 12 oz. mitted aged 1 hour Very little air entry could be detected, l recession was pronounced Radiographs taken at 9 hours hours and immediately after death showed good expansion the first film showed some very fine mottling At necropsy the lobes floated but the lower lobes were poorly aerated. rtial atelectasis was general but there was no hyaline mbrane Death was due to bilateral intraventricular morrhage

e radiological appearances in this case were not ll marked but might be classed as equivocal

Discussion

Different kinds of radiographic shadows are sometimes visible when hyaline membrane is present They represent a type of atelectasis associated therewith they are not specific of the lesion but tend to follow a definite sequence Three main types can be distinguished, all of which may be present at the same time or they may follow in quick succession in hours or days

At first fine miliary mottling more or less uniformly distributed throughout the lung fields is noticeable It appears within a few hours of birth and is probably due to diffuse alveolar collapse and alveolar consolidation. Caffey (1945) described a similar appearance and claimed that this was a physiological phenomenon in premature babies and represented small areas of atelectasis which called for no treatment and resolved within days or weeks He ascribed it to structural immaturity of the alveolar buds, citing Farber and Wilson (1933) We submit that these appearances are not physiological and we have traced their development in patients in whom hyaline membrane has been found at necropsy This mottling is not an attribute of prematurity per se, because clear lung fields are often demonstrable in unaffected premature infants. If the clinical course is progressive and down hill, this fine mottling becomes coarse and tends to coalesce Ultimately the shadows become confluent, until definite lobar or lobular consolidation and collapse are recognisable. If on the other hand, the condition improves, the initial mottling slowly resolves and ultimately the lung fields become clear In some instances all three shadows—miliary mottling coarse mottling and consolidation and collapse—are present in the same lung

Donald and Lord (1953) illustrated radiological changes of the above description without specifying at the time the radiological sequence of events and the diagnostic significance of these findings Meschan et al (1953) have described a further case and recommend an extended study

Once the coarse mottling has developed and areas of consolidation and collapse have appeared, the bronchial tree can at times be clearly seen outlined into its minor divisions particularly in the mid and lower zones This outlining of the bronchial tree is not found in primary atelectasis, when the lungs are totally opaque and only the trachea may be visible

The sequence of miliary mottling coarse mottling and lobar consolidation and collapse seems to be found only when hyaline membrane is present The reverse sequence of pulmonary collapse and subsequent resolution we have seen in pulmonary infection and in some cases of primary atelectasis

Summary

The assistance which radiology has to offer in the assessment of atelectasis of the newborn and the diagnosis of hyaline membrane during life is discussed.

Twenty-eight cases are described, from a study of which it appears that not only may diagnosis be clarified but also three distinct radiological patterns are discernible according to the stage of development of hyaline membrane.

The necropsy studies were made mainly by Dr A E. Claireaux, and we are indebted to him for his expert help Our thanks are due to Prof A Moncrieff for his continuing support and to members of the radiographic staff who have cooperated at all hours of the night This research is being assisted by a Leverhulme scholarship awarded to one of us (I. D) by the Royal College of Obstetricians and Gynæcologists

With illustrations on plate

As part of a clinical investigation of a large series of patients with chronic bronchitis (Oswald et al 1953), standard postero anterior chest radiographs of each patient were taken in suspended full inspiration The films of 857 of these patients have been studied with a view to determining whether there are any characteristic radiological features of chronic bronchitis, and whether there is any correlation between the clinical severity of the bronchitis and the presence or absence of any of the radiological signs commonly regarded as indicating emphysema

Bronchograms done in a representative group of 90 patients have also been studied

Review of Standard Chest Radiographs

Each radiograph was assessed by a radiologist (G S) who knew that the patients were suffering from chronic bronchitis, and (when he asked) was informed of their age and blood-pressure readings At the time of the assessment, he had no other clinical information

APPEARANCES SUGGESTING EMPHYSEMA

The criteria used for making a radiological diagnosis of emphysema were

(1) *A low flat diaphragm* —Owing to the film shortage at the time of these observations, only a single radiograph was taken in each case , hence the range of diaphragmatic movement could not be assessed

(2) *A narrow vertical heart with a prominence of the left border* just below the aortic knuckle, suggesting enlargement of the main pulmonary artery

(3) *An abnormal vascular pattern*—i e , clear prominent vessels in the region of the hila, which narrowed considerably after the early branchings in the lung fields These vessels were not only unduly narrow but appeared, as they proceeded distally, to be reduced in number compared with those seen in radiographs of normal persons, and they tended therefore to be abnormally widely spaced

(4) *Bullous changes* —A bulla was held to be present when a localised translucent area 1–10 cm in diameter, with a white hair line margin, was seen , and a bullous area was presumed when a poorly demarcated hypertranslucent area was seen without vascular shadows, or with a few apparently greatly narrowed vascular shadows within it

A radiological diagnosis of emphysema was made when all four signs were present, and occasionally when only the last three, including definite bullæ, were seen These criteria were satisfied in 128 (15%) of the whole series

Excessive visibility of large pulmonary vessels in the middle of the lung fields was not regarded as a sign of emphysema , nor was hypertranslucency of the whole or a part of the lung fields regarded as reliable evidence in the absence of the other criteria mentioned above The shape of the thoracic cage and calcification of the costal cartilages were ignored as factors in the diagnosis , in fact excessive calcification of the costal cartilages was noted with no greater frequency in those patients considered to have radiological emphysema than in the rest of the series

The patients who were thought not to have undoubted radiological evidence of emphysema could be subdivided into those with only some of the radiological featu emphysema and those with none (table I)

As part of the clinical investigation, these pa had been classified into six grades according to exercise tolerance , those in grade 0 had no dy grades 1, 2, and 3 had increasingly severe exert dyspnœa , patients in grade 4 were incapacitated dyspnœa on the slightest exertion , and those in gr were dyspnœic at rest The radiological appearance compared with the exertional capacities of the pa in table II, which shows a direct correlation between degree of dyspnœa and the frequency of the radiol demonstration of appearances suggesting emphy The presence of only some of the radiological suggestive of emphysema does not seem to have any relation to the exercise tolerance, which confirms belief of Knott and Christie (1951) that most of radiological signs said commonly to be associated emphysema “ if taken alone, are of doubtful diag significance ”

In some patients dyspnœa may have been due mo bronchospasm than to emphysema, and this may ac for the comparative infrequency with which a radiol diagnosis of emphysema was made in the incapac patients Another probable explanation is the con tive manner in which the radiological appearances assessed, the criteria described above being st adhered to It is also possible that small emphysem spaces, which often involve only primary or seco lobules (Reid 1953), may be invisible on a radiogr even if collectively they occupy a considerable

TABLE I—INCIDENCE OF RADIOLOGICAL FEATURES SUG EMPHYSEMA IN 857 PATIENTS WITH CHRONIC BR

—	No of pa
Undoubted radiological evidence of emphysema	128 (1
Some radiological features only insufficient to justify a diagnosis of emphysema	320 (3
No radiological features of emphysema	409 (4

OTHER RADIOLOGICAL ABNORMALITIES

Table III shows that in this group of patients chronic bronchitis radiological changes other than suggestive of emphysema were rare

The term “ inactive pulmonary tuberculosis ” w to signify small circumscribed dense or calcified confined to a small part of the lung, usually in the zones

The commonest pleural abnormality was “ thicken often with an overlying rib resection denoting empyema The high incidence of pleural abnorm may be related to the large number of chronic bronch whose symptoms date from an acute pulmonary infe and to the frequency with which pneumonia compli chronic bronchitis In 7 of the 11 patients with segme or patchy consolidation there was no obvious cons tional upset and the radiological opacities disapp within a few weeks , these patients (0 9% of the series) presumably had localised aspiration pneu of the type described by Scadding (1951)

The radiographs of the two patients with sponta pneumothorax, which had caused no symptoms in e case, showed generalised emphysema

NORMAL RADIOGRAPHS

Of the whole group of 857 radiographs 354 (4 were considered to show no abnormality in the fields

Bronchographic Appearances

Bronchograms were done in 90 patients who form representative group of chronic bronchitics. Fewe

LE II—COMPARISON OF RADIOLOGICAL APPEARANCES WITH EVERITY OF DYSPNŒA IN 857 PATIENTS WITH CHRONIC RONCHITIS

idence of radiological appearances in each clinical grade is expressed as percentage)

—	104 patients with no dyspnœa (grade 0)	304 patients with dyspnœa on heavy work (grade 1)	248 patients with dyspnœa on hurrying (grade 2)	154 patients with dyspnœa on walking (grade 3)	47 patients incapacitated by dyspnœa (grades 4 and 5)
iological em ysema	5	7	20	25	26
o radiological atures of em ysema	37	38	34	44	32
radiological atures of em hysema	58	55	46	31	42

ients were examined by bronchography than by ndard chest radiography but the distribution of ical severity and the sex incidence were comparable he two groups

VARIATION OF BRONCHIAL CALIBRE

Normally on respiration the bronchi vary in calibre oming wider on inspiration and narrower on expira- In 77 of the bronchograms films were taken in pended full inspiration and expiration to demonstrate range of variation In 2 bronchograms both of men h incapacitating chronic bronchitis generalised exces inspiratory dilatation was seen, the expiratory nchial calibre being normal. In bronchograms of 21 er patients similar excessive variation in calibre was n involving only a part—usually one or more mental branches—of the bronchial tree (figs 1A B)

Our experience of the bronchographic appearances on piration and expiration in normal people is inadequate, are the published references to this subject but ually even with the maximal respiratory movements variation is slight and the inspiratory calibre of medium-sized bronchus does not exceed one and a f times the calibre on expiration In these chronic nchitics considered to show excessive variation the piratory calibre was usually at least twice the expira y calibre, but admittedly accurate measurements are possible Chronic bronchitics especially those with ch dyspnœa, are not good subjects for bronchography l under these conditions it was often difficult to obtain isfactory respiratory excursions had this not been a higher incidence of excessive variation in bronchial ibre might have been observed and also a more wide- ead distribution of such changes throughout the nchial tree

BLE III—INCIDENCE OF RADIOLOGICAL ABNORMALITIES OF UNG FIELDS EXCEPT THOSE SUGGESTING EMPHYSEMA IN 857 CHRONIC BRONCHITICS

Radiological abnormality	No of patients showing abnormality
ctive pulmonary tuberculosis	61 (7%)
normal pleural shadows	50 (6%)
neycomb or "tubular" shadowing	12 (1 4%)
ar shadows (localised fibrosis)	12 (1 4%)
mental or patchy consolidation	11 (1 3%)
neralised reticulation	4 (0 5%)
ntaneous pneumothorax	2 (0 %)

BRONCHIAL DILATATION

In the bronchograms referred to in the last paragraphs the bronchial calibre on expiration was normal in 19 bronchograms however, there was local bronchial dilatation which persisted throughout both phases of respiration In 14 of these patients the appearance of the dilated bronchi was unusual, an irregular beaded appearance being produced by short and usually unequal segments of alternate dilatation and narrowing (fig 2) This beading was most frequently seen in one or more of the medium sized bronchi of the lower lobes, and was usually associated with absence of filling of the minor branches of the affected bronchus The incidence of these lesions bore a closer relation to the duration of the bronchitis than to its severity from this and from their localisation it seems possible that they result from past minor aspiration pneumonias being similar to some of the persistent bronchial changes which Morle and Robertson (1953) described as a sequel to such episodes In 4 patients a local cystic dilatation of one branch of an upper lobe bronchus was seen probably representing past tuberculosis A local dilatation of the left upper lobe and lingular bronchi which was seen in the films of 2 patients was unusual in that transverse striations were present, due to ridges in the bronchial lining

BRONCHIAL DIVERTICULOSIS

The commonest abnormality was diverticulosis of the main or of the lobar bronchi which was present in 45 (50%) of the bronchograms (fig 3) These outpouchings of the bronchial lumen were multiple and were usually seen on the inferior surface of the bronchi especially those of the upper lobes and lingula They are due to dilatations of the ducts of mucous glands (Reid 1953 Duprez and Mampuys 1953) One of the first accounts of bronchial diverticulosis by Morlock and Pinchin (1933) described in the same chronic bronchitic "dilatation of the trachea and the whole bronchial tree" with "irregularity of the smaller bronchi shown by beading" Bronchial diverticulosis occurs rarely if at all in bronchograms of normal people, and if seen diffusely in bronchiectatic patients it probably signifies a coincident generalised bronchitis

BRONCHOGRAPHIC EVIDENCE OF EMPHYSEMA

In only 1 patient had the iodised oil entered an emphysematous bulla but in 11 patients the bronchial pattern was distorted by bullæ. A common appearance which seems to bear a direct relation to other radiological evidence of emphysema was the termination of the iodised-oil pattern peripherally in small berry like opacities about 1–3 mm in diameter for which the name "peripheral pooling" is suggested (fig 4) Peripheral pooling was seen in 14 (67%) of the 21 bronchograms of patients whose standard radiographs suggested emphysema, and in only 12 (17%) of the 69 other bronchograms Absence of filling of the small peripheral bronchi was noted in many of the bronchograms, often distal to bronchi showing beading or distal to otherwise normal bronchi at the bases, which are the parts of the lungs where filling with iodised oil is usually most adequate In most cases this appearance was probably due to disease in the bronchioles but as such absence of filling may be due to technical failure, no accurate estimate of its incidence is possible

SPIDER BRONCHI

Generalised narrowing usually only apparent [illegible] to the third or fourth generation of bronchi was [illegible] in 4 bronchograms in none of these patients [illegible] bronchospasm severe A similar appearance [illegible] occasionally in normal people and its [illegible] is uncertain

TABLE IV—INCIDENCE OF PRINCIPAL BRONCHOGRAPHIC ABNORMALITIES IN 90 CHRONIC BRONCHITICS COMPARED WITH SEVERITY OF DYSPNŒA

(Expressed as percentages of patients in each clinical grade showing abnormality)

Clinical grade	Excessive variation of calibre	Diverticulosis	Localised bronchial dilatation	Peripheral pooling
15 patients with no dyspnœa (grade 0)	23	33	13	20
63 patients with dyspnœa on exertion (grades 1, 2, and 3)	31	52	19	29
12 patients incapacitated by dyspnœa (grades 4 and 5)	33	58	42	42

INCIDENCE OF BRONCHOGRAPHIC ABNORMALITIES

Table IV compares the incidence of the principal bronchographic abnormalities in the three clinical grades of dyspnœa In each case the incidence rises as the degree of dyspnœa increases 71 patients (79%) had some bronchographic abnormality, and in many, especially those more severely affected, more than one abnormality was present

Discussion

Chest radiographs are essential in the diagnosis of chronic bronchitis, because patients with other serious chest diseases often present with symptoms of this condition Once the clinical diagnosis of chronic bronchitis has been established, the value of chest radiography is less certain This study of single standard chest radiographs shows that, except for occasional minor changes, the only abnormalities are those which are commonly regarded as indicating emphysema The difficulties of the radiological diagnosis of this condition have been discussed by Knott and Christie (1951) In this survey we have insisted on three particular radiological signs—a fourth being often present in addition—before a radiological diagnosis of emphysema was made According to these criteria a direct correlation between the degree of dyspnœa and the frequency of the radiological diagnosis of emphysema has been found This suggests that the strict application of these criteria may be of value in the diagnosis of emphysema

Although in chronic bronchitis abnormalities are seen more frequently on bronchograms than on standard chest radiographs, bronchography is of less clinical value Lesions such as gross bronchiectasis and, more rarely, bronchial carcinoma can be excluded, and some estimate can be made of the degree of permanent damage present, this may be of importance if the surgical treatment of emphysema is further explored The bronchographic findings do not provide much help towards the understanding of the increased sensitivity of the bronchial tree in chronic bronchitis or of the causes of the disabling dyspnœa Reid has emphasised that the irreversible pathological changes which take place in advanced stages of chronic bronchitis affect chiefly the peripheral parts of the bronchial tree Her work confirms the important pathological significance of our bronchographic findings, the most remarkable of which are the "peripheral pooling" and the distortion and poor filling of the small peripheral bronchi and bronchioles

Summary

Standard chest radiographs of 857 patients with chronic bronchitis were examined

128 patients (15%) had radiographic changes suggestive of emphysema, the occurrence of such changes being directly related to the degree of dyspnœa Radiological evidence of emphysema was seen in only 26% of the patients who were incapacitated by dyspnœa The [illegible] used to make a diagnosis of emphysema were a low flat diaphragm, a narrow vertical heart with nence of the pulmonary artery, an abnormal pe vascular pattern, and evidence of bullæ

In 320 patients (37%) some of the radiological malities associated with emphysema were noted, appearances were not thought to be sufficient to a radiological diagnosis of emphysema

No other appearances which might be characteris chronic bronchitis were found, and in 354 (41%) of films there were no abnormalities in the lung fields

Bronchograms of 90 patients with chronic were examined, of which 79% showed some abnor The principal abnormalities were excessive varia the bronchial calibre on respiration, localised bronchial dilatation, bronchial diverticulosis, "peri pooling," and poor filling of the smaller bronch bronchioles

The value of standard chest radiographs and br grams in the diagnosis and assessment of p chronic bronchitis is discussed

We wish to thank Dr Neville Oswald for the of studying the radiographs of patients with chronic br seen in his clinics at Brompton and St Bartholo Hospitals

With illustration on plate

THE fact that a thorium sol injected into an made the liver and spleen opaque to X rays was discovered by chance in 1929 by a Japanese w Oka (1930) Radt (1930) prepared a thorium dio which became available for clinical use under the 'Thorotrast' It is a suspension of thorium d (about 200 mg per ml) with an average partic of 3–10 mμ Reports were published on its us hepatolienography, retrograde pyelography, and graphy

Thorium in the Body

Intravenously injected thorium dioxide is taken up the reticulo endothelial system and slowly excreted the kidneys Thorium salts may also be excreted the bile (Salerno and Mattis 1951)

Thorium and its decay products are radioactive emit alpha and beta particles and gamma rays. emissions damage living tissues by producing in their path (Zirkle 1936, Lea 1947) From the follo table (adapted from Zirkle 1933) it is seen that practical purposes, and so far as internally depo radioactive substances are concerned, only alpha p need be considered

	Range in tissues	*Track* (ion pairs
Alpha particles	30–50 μ	40
Beta particles	0 5–5 0 mm	150
Gamma rays	Comparable to X rays	

The metabolism of injected thorium is complicat the fact that its decay products differ from it chem othorium 1 and thorium X are isotopic with radium like it, are deposited mainly in the inorganic roxyapatite lattice of bone, or tend to migrate there ormed elsewhere Thoron is a gas and enters the od About 0 1% is excreted by the lungs, the rest ntegrating rapidly to thorium A before this can open (Aub et al 1952) However most of the alpha ticles are released and most of the damage is done, he liver spleen, and bone marrow

he biological effects of radiation include severe or ial biochemical disorder inheritable change and plasia (Duggar 1936 Lea 1047 Bloom 1048 Tansley al. 1948, Dale 1951) Nevertheless thorium compounds pite warnings about their radioactivity (*Journal of American Medical Association* 1937 Taft 1937a) e been used diagnostically for many years Whitaker al (1033) limited its use to moribund patients and to se where the risks were overshadowed by its value in gnosis They demonstrated thorotrast granules in Kupffer cells and in scattered granules between the enchymal cells the long term effects were not died Willis (1048) said :

> While no tumours following the use of thorotrast in man e yet been reported, the risk that such may appear during next decade or so when due time has elapsed following use of this relatively recent method of diagnosis must be gnised "

elbie (1938) found that 40% of rats injected with rotrast developed sarcomata Thomas et al (1951) iewing the literature and addressing a questionary 167 radiologists were able to describe only 5 instances malignant growths following the injection of thoro at they concluded that this did not indicate a cinogenetic effect in man, but they thought that osis in the liver and spleen and at the site of an ravascular injection was a risk which made the use thorotrast unjustifiable They do not give details of ases (2 of liver tumour and 1 of leukæmia) but the er 2 can be summarised as follows

woman, aged 40 was given intravenous thorotrast 75 ml investigation of a lump in the liver diagnosed later as a oma (MacMahon et al 1047) For twelve years she ained normal. When she died at the age of 70 she was nd to have a hæmorrhagic primary endothelial-celled oma of the liver This arose in relation to the largest ount of thorotrast in the body Many of the tumour cells tained thorotrast.

similar appearance was noted by Rigler et al (1935) person with a primary liver tumour who was given an ection of thorotrast)

man, aged 48 had retrograde pyelography done with rotrast 30 ml Sixteen years later a spindle-celled sarcoma he kidney was found at operation. There was a massive ount of thorotrast next to the tumour

is is a rare renal tumour but the usual one found in mals after the injection of thorotrast It was therefore that thorotrast had caused the growth in this case llinger 1949)

Abrahamson et al (1050) reported the case of a patient o died with bilateral alveolar-celled carcinoma of the gs sixteen years after an injection of thorotrast 75 ml e liver and spleen contained thorotrast but thorotrast s not demonstrated in the lungs which were not lioactive and we do not think a causal relation p has been shown between the thorotrast and the cinoma.

pler et al (1017) reported a case of aplastic anæmia lowing intravenous administration of an unknown e of thorotrast nine years previously At necropsy marrow showed aplasia and deposits of thorotrast. orium dioxide constituted 5% by weight of the rrow Since the active marrow of an adult weighs out 700 g (Wintrobe 1051) this implies the presence the marrow of 35 g of thorium dioxide and an initial ection of at least 175 ml of thorotrast However irregularity of deposition may explain the high concentration of thorium in the sample of marrow examined Sections of the liver from this case were examined by Yagoda (1040) by autoradiography Calculations based on these studies showed focal concentrations of 3% of thorium dioxide

Schmidt et al (1050) mention a patient who had an unstated amount of thorotrast injected for cerebral arteriography and ten years later developed aplastic anæmia Deposits were shown radiographically in the marrow spleen and lymph nodes, but their radioactivity was not demonstrated.

The presence of radioactive substances in a living person may be shown by detecting radioactive gases (radon or thoron) in the breath (Martland et al 1025) thorium X in the fæces, or gamma rays emitted from the body (Taft 1037b) A full account of the elaborate methods used is given by Aub et al (1952) Autoradiography however is a method practicable in any pathology laboratory by means of which radioactive deposits may be demonstrated in tissues obtained by biopsy or necropsy

In the following case the diagnosis was confirmed during life

Case-history

A bachelor aged 52 was first seen in November 1952 Twenty three years previously thorotrast (probably 10 ml) had been injected into the arteries of the right leg in the investigation of some arterial disease for which the leg was later amputated. He remained well and active after this apart from bouts of "indigestion"—i.e attacks of upper abdominal pain which, he thought followed emotional upsets

On examination the liver edge was just palpable but the spleen could not be felt All the investigations made were negative except that films taken during cholecystography (which was normal) showed the liver and spleen to be full of a fine dense radio opaque substance giving a fine reticular appearance (fig 1) Radiography of the skeleton showed no abnormalities.

HISTOLOGICAL FINDINGS

Needle biopsy of the liver was performed the aspirated tissue being fixed in formalin and embedded in paraffin wax Sections showed liver of normal architecture but containing scattered deposits (about 20 in an area of 2 5 sq mm) Most of the deposits filled the cytoplasm of what appeared to be groups of 10–20 parenchymal cells but possibly these were clusters of swollen Kupffer cells (fig 2) Occasional deposits filled single parenchymal cells or Kupffer cells. Considerable amounts lay in the portal tract connective tissue which was fibrotic Small deposits lay freely between liver cells or in sinusoids, although this appearance may have been due to material shifted by the microtome knife The deposits were sharply outlined finely granular greyish, translucent and refractile. A few tiny granules were scattered throughout the tissues without forming discrete masses There was neither excessive cellular infiltration nor architectural disorganisation but all the nuclei of the parenchymal cells showed an

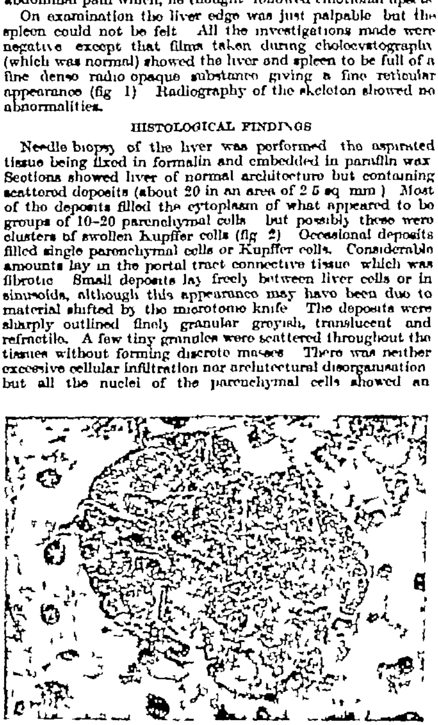

Fig 2—Deposit of thorium dioxide in liver cells. (Saffranine. × 1236.)

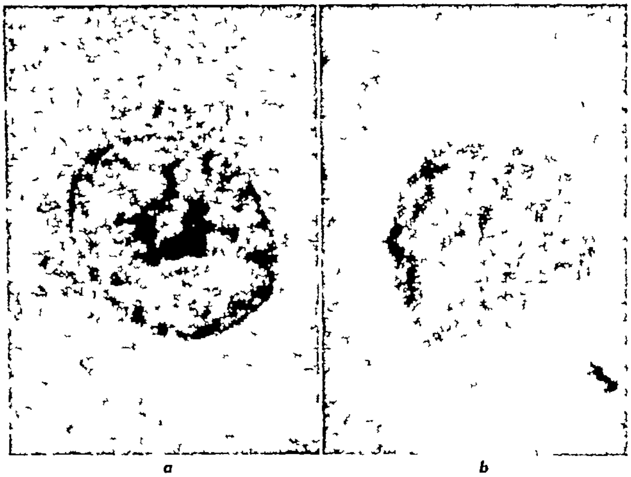

Fig 3—a, Normal liver-cell nucleus showing stringy chromatin in colourless nucleus sap and bounded by well-demarcated nuclear membrane b, abnormal liver-cell nucleus containing granular chromatin and bounded by abnormally thin nuclear membrane (Feulgen × 8000)

abnormality which may be significant The normal liver cell nucleus shows a sharply defined varicose chromatin network suspended in a colourless nuclear sap (fig 3a) The nucleolus is generally surrounded by a conspicuous condensation of chromatin, the "nucleolar associated chromatin," said to be concerned with the synthesis of protein (Thorell 1947, Caspersson 1947) In the present case the nuclei were uniformly filled with a fine peppery granular chromatin (fig 3b) The nucleolar associated chromatin was generally diminished in amount The nuclear membrane was abnormally thin

On the whole, the nuclei were slightly smaller than normal, particularly those of the cells containing deposits, but it is difficult to be certain of this in routinely processed material Though these changes could be appreciated with any nuclear stain, they were best shown by the Feulgen technique (fig 3) No mitotic figures or cytoplasmic abnormalities were seen

We have not seen such a strikingly uniform abnormality in any of the numerous other liver biopsy specimens which we have studied In particular the nuclei of pyknotic liver cells, which they most resemble, are much more uneven in distribution and show much more irregularity in staining and outline

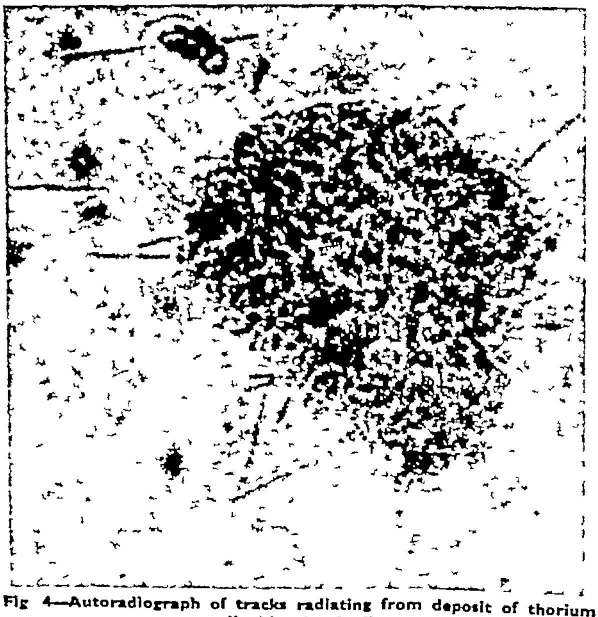

Fig 4—Autoradiograph of tracks radiating from deposit of thorium dioxide (× 1236)

Abundant glycogen was present, even in on those containing deposits, although it could demonstrated in these However, chemically glycogen may show a considerable decrease before apparent histologically (Morrione and Mamelok

RADIOACTIVITY

The radioactivity of these deposits was by using alpha-track plates, in which the produced by the passage of an alpha particle silver bromide, rendering the track visible after ment of the plate (For a full discussion see 1949, Doniach and Pelc 1950, Heller 1951) The of Endicott and Yagoda (1947) was followed.

Paraffin sections 3 μ thick were mounted on emulsion, and the plates were stored for twenty The wax was then removed, the plates were and the sections were stained with Meyer's and mounted in D P X mounting medium

A typical result is shown in fig 4, in which radiating from the deposit are seen in the About 100 tracks are seen per section This about half the alpha particles emitted, the other travelling away from the emulsion

The amount of thorium in the liver can be calculated, on the assumption that the deposits thorium in equilibrium with its decay products, and the biopsy is a fair sample of the liver, as follows

Volume of section	= 0 0075 c.mm.
Equivalent volume of unfixed liver	= 0-0125 c.mm. based on
Number of sections in a liver 1500 c cm in volume	= 1 20 × 10'
Number of alpha particles emitted in liver in 20 days	= 2 40 × 10''
Number of alpha particles emitted by thorium 1 g in 20 days	= 4 34 × 10''
Mass of thorium in liver	= 0 55 g

This is equivalent to thorium dioxide 0 63 g or thorotrast

If the original injection was 10 ml , this indicates 30 % of the total dose remains in the liver at Jacobson and Rosenbaum (1938), basing their lations on gamma-ray measurements, found that of injected thorotrast remained in the liver after years

In the present case, therefore, the liver has shown to contain radioactive deposits, and deposits may be presumed to be present in the (which was radio-opaque) and bone-marrow We say with certainty whether the nuclear changes represent radiation damage or not

Bloom (1948) irradiated numerous species of animals various external and internal sources He observed of chromatin and increased clarity of nuclear detail. ever, his experiments, like many others which have published, were short term and involved relatively radiation

Tripoli (1934) observed pyknosis of liver nuclei in but only when ten times the standard dose was photomicrograph of the liver in a case reported by and Chase (1936) shows increased nuclear basophilia, similar photograph in the case reported by Jacobson Rosenbaum (1938) shows vacuolated nuclei In neither does the author comment on these appearances

In general, the photomicrographs hitherto of thorotrast deposits in man do not show any of the nuclei

Discussion

The dangers of the presence within the body of amounts of radioactive matter have often been demonstrated (Martland 1926, 1929, 1931, et al 1925) In spite of this it is still the practice of radiologists to give as much as 75 ml of (Pirkey et al 1951, Loeb et al 1952) This equivalent to 1–3 μg of radium (*Journal of the Medical Association* 1937) As an illustration of this amount of radioactive substance may the cases of chronic radium and mesothorium reported by Aub et al. (1952) may be considered

In their series there were 13 patients with a body of radioactive material equivalent to 0 5–3 0 μg of these 2 were crippled by pathological fractures and 1 eloped a giant-cell tumour of the jaw 1 an osteogenic oma and 2 a carcinoma of the nasal sinuses. The carci mas did not appear until more than thirty years after the tial exposure

ince thorotrast has been in general use for little re than twenty years it is not surprising that few ths attributable to its radioactivity have so far been orted. If a person dies of a malignant tumour unless quate histological examination of post-mortem tissues made, it will not be realised that the growth may be to a single injection received twenty years previously l perhaps long forgotten

There is much to be said for limiting the use of thoro st to shed light on difficult diagnostic problems in erly patients, where its use may prevent or expedite najor operation Pirkey et al (1951) who adopted se indications used it only seven times in 100 000 uninations.

Summary

Reports of thorotrast deposits in man mention 7 deaths ributable to the radioactivity of thorium

The doses of thorotrast commonly used are carcinogenic

The demonstration of radioactivity in tissues does t require expensive materials, special preparation the tissue, or elaborate technique. It should be empted whenever routine histological examination eals deposits which are possibly thorotrast or other lioactive material

In this way the difficulty of assessing the true incidence thorotrast-induced tumours in man might be ninished.

Our thanks are due to Dr R H Herz, of Kodak Research boratory for the alpha track plates and to Mr H. Knight the photographs.

ASEPTIC NECROSIS OF BONE IN CAISSON DISEASE

JAMES RONALD
M.D Edin. F R C P.E
PHYSICIAN ROYAL NORTHERN INFIRMARY AND
RAIGMORE HOSPITAL, INVERNESS

With illustrations on plate

CAISSON disease decompression illness, or the bends' develops when a person who has been working in an atmosphere of compressed air undergoes decompression too rapidly Excess nitrogen (in the form of bubbles) is released within the body causing tissue damage Bert in 1880 suggested that this was the mechanism involved and the work of Boycott Damant and Haldane (1908) and Bornstein (1910 1914) has since confirmed the hypothesis The clinical features are those of injury usually transient, to different systems—cerebrospinal (varying from paræsthesiæ to unconsciousness) cardiovascular (embolic) pulmonary (dyspnœa), visceral and urogenital (nausea vomiting and pain), dermal (pruritus and lividity) and skeletal (Erdman 1913) Affection of the bones is commonly associated with pain, often so severe as to produce the characteristic distortion of posture from which the name the bends originates

That permanent changes take place in the bones was shown by Bornstein and Plate (1911) and by Bassoe (1911 1913) independently when they described the radiological appearances of mottled changes in density in the head of long bones, with flattening of the articular surface, narrowing of cartilage space and marginal lipping The changes have since been recognised as those of aseptic bone necrosis (Coley and Moore 1940) The condition is not common and a case is reported here

Case report

A man, aged 62, was admitted to hospital with pain in the chest after a fall; he had also had discomfort in the left wrist He had been employed in Great Britain as a diver for more than forty years and had worked almost every day up to six hours, wearing a diving suit into which air was pumped from compressors on the deck above He had worked at depths of 60–80 ft He estimated that on the average he had periods of two hours submerged with short intervals for rest between In diving he reached 80 ft in about ten seconds coming up he stopped at 40 ft for ten minutes, 30 ft for ten minutes and 10 ft for fifteen minutes to decompress before surfacing

History of Bends

He had had the bends more or less constantly and at least once a week had a severe attack, usually on a Monday The attacks were of two kinds— bad and mild The bad type came on if he had been working deeper than 60 ft When he came into the fresh air he would develop a sick feeling in the abdomen, his face became greyish yellow and he had vague general pains followed by sudden agonising pains in the joints—e g shoulder and knee These pains were severe for an hour or two and gradually passed off in five or six hours. When they were exceptionally severe a local anæsthetic injected into the skin over the joints gave some relief. After the pains had disappeared the limbs were relatively anæsthetic and for some hours there might be some incoördination of walking In the mild type of attack which he called skin or plum pudding bends his whole body became blue-white and intensely itchy This was rapidly relieved by a very hot bath He could feel air bubbles under his skin This lasted about twenty four hours and he could hardly bear to have his skin touched because it was tender as well as itchy His trunk was particularly affected.

During his work he was usually examined medically once a year and he had worked considerably later in life than the average diver who usually gives up this work about the age of 50

Investigations

He was a well built man showing no evidence of distress and general clinical examination revealed no abnormality in the vascular nervous or other systems.

A *blood count* showed red cells 5,220,000 per c mm , Hb 100%, white cells 7500 per c mm , polymorphs 57%, lymphocytes 31%, monocytes 7%, eosinophils 5%, erythrocyte sedimentation rate 8 mm in 1 hour (Westergren) , Wassermann reaction negative

The *urine* contained no abnormal constituents and no excess of calcium (Sulkowitch test)

An *electrocardiogram* was within normal limits

Radiography showed no abnormality of the heart or of the lungs, but it showed intramedullary calcification of the lower end of each femur, the upper end of each tibia, and the upper end of each humerus The calcification started from the region of the epiphyseal line, extending thence into the shaft of the bone The cortex was not involved, and the bone was not expanded (figs 1 and 2)

Biochemical findings—Serum calcium 10 mg , serum-phosphorus 4 5 mg , serum alkaline phosphatase 4 2 units, serum acid phosphatase 2 0 units, and blood cholesterol 118 mg per 100 ml , calcium balance normal

Discussion

Aseptic necrosis of bone does not necessarily give rise to symptoms unless it involves the articular surface of a joint Its primary cause is interruption of the blood-supply, with subsequent death of bone It can be produced experimentally by the injection of irritants (Bancroft 1922), by mechanical blockage of vessels e g , with charcoal solution (Kistler 1934), by periosteal stripping (Brunschwig 1930), and by air embolism (Colonna and Jones 1948) Its production in caisson disease is perhaps slightly more complex than at first appears

When the body is subjected to compressed air, the fats and lipoids absorb five times as much nitrogen as do the non-fatty tissues The main deposits of fat are in the abdomen, central nervous system, and long bones The bone marrow and spinal cord are, in relation to the nitrogen content, the tissues with poorest blood supply, and they are enclosed in bone, which prevents the diffusion of nitrogen into the adjacent tissues If decompression takes place too suddenly, nitrogen is released in excess of what can be excreted by the lungs Nitrogen stasis occurs, with the formation of bubbles in the blood and tissues, particularly where the saturation is high or the blood flow slow—the sites already mentioned The cortex of the bones is spared by virtue of its rich blood supply, and the lesions are usually confined to the diaphyses, but metaphyseal and articular lesions can occur The location and severity of symptoms depend on the site affected and the volume of gas released

The gas bubbles have a mechanical action in both intravascular and extravascular sites in blocking the blood-flow Furthermore, compression tends to increase the intravascular agglutination of erythrocytes (James 1945), and this agglutination is intensified as the carbon-dioxide tension increases (Swindle 1937) The obstruction of the blood-vessels is completed by their inability to expand against the rigid walls of the bony tube in which they are confined Consequently infarction of the bone occurs

The changes which ensue take a considerable time to develop but nevertheless may follow even one faulty decompression The pathology is that of bone necrosis and infarction Within the shafts of the bones necrotic areas are found surrounded by a fibrous wall Calcification and ossification take place, and the place of the dead bone is partly taken by new bone (Kahlstrom et al 1939, Walker 1940) Radiography reveals an irregular area of increased density usually surrounded by a thin band of calcification The medulla beyond appears normal The lesions are multiple and restricted to the long bones

In the differential diagnosis must be considered chronic sclerosing osteitis (rarely multiple, and usually showing cortical thinning and medullary narrowing), sclerosing osteogenic sarcoma (pain, ill defined border, and of calcified boundary), calcifying enchondroma (
symmetrical, and expansile), syphilitic osteitis (pa
and serologic reaction), and tuberculosis (
new bone)

Treatment is directed towards the preventi
deformity and its correction if necessary The
can be prevented by adequate decompression

From the Department of Pharmacology and the Depart Medicine, Oxford

The presence of minute traces of radium in the
has long been recognised as a serious toxic hazard
cause blood dyscrasias and bone tumours (Martland
1925, Aub et al 1952) Hamilton (1947) has p
that a large number of the radioactive product
uranium fission are also selectively retained in
skeleton, while the strontium isotopes are " par exce
producers of bone tumours " (Brues et al 1946,
1949) The deposition of these radioactive is
appears to follow one of two patterns The deposit
strontium follows the same route as that of cal
(Kidman, Rayner, Tutt, and Vaughan 1952, J
Rayner, Tutt, and Vaughan 1953) The depositi
yttrium and the rare earths differs from that of stro
in that immediately after injection it is found in c
areas of active growth only (Hamilton 1947, R
Tutt, and Vaughan 1953)

Attempts to increase the normal extremely slow
such isotopes from bone proved disappointing (Vau
Tutt, and Kidman 1952) until an increased ur
excretion of yttrium in rats was reported (Forema
Hamilton 1951, Cohn et al 1953) following the adr
tration of calcium and sodium salts of ethylene di
tetra acetic acid (versene or E D T A) Ethylene di
tetra acetic acid is a chelating agent which has m
ability to form soluble complexes with cations in sol
Chelation occurs most readily with certain metal
as copper and lead and the rare earths On theo
grounds it should form a chelate with yttrium, wh

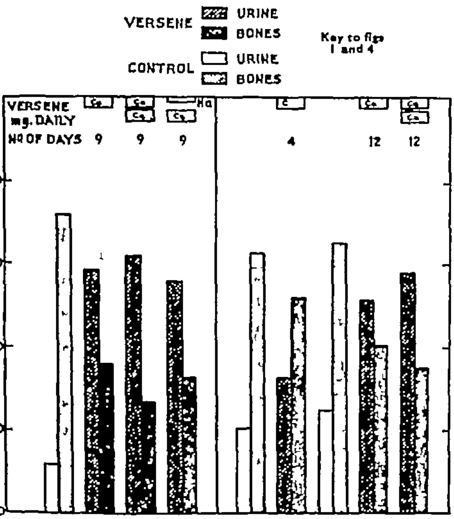
on Medical and Biological Application of Nuclear P



—Excretion and retention of ^{91}Y in rabbits (5–7 weeks old) following daily administration of versene.

um, are held less strongly No chelation occurs with h metals The sodium salt is known to be toxic to als (Bersworth Chemical Company 1952) though necessarily to man (Spencer et al 1952) since tion occurs with calcium following injection and calcæmia may result The calcium disodium salt he other hand, appears to be non toxic (Bersworth nical Company 1952, Spencer et al. 1952) and is lly excreted Preliminary observations suggest that salt is of value in treating lead poisoning both in lren and adults (Sidbury et al 1953)

e following report describes experiments on the tiveness of sodium and calcium ethylene diamine acetic acid in removing ^{90}Sr ^{90}Y and ^{91}Y from the ton of rabbits.

Experimental Procedure

abbits of the same stock as those used in previous riments (Kidman Tutt and Vaughan 1950) were in metabolism cages so that urine and fæces could be collected separately They were aged 5–7 weeks or over 12 months and were given a single intravenous injection of either ^{91}Y or ^{90}Sr–^{90}Y equilibrium mixture (25 μc per kg) This was followed by intraperitoneal injections of calcium disodium versenate or trisodium versenate at various intervals The dose given was an arbitrary one The young rabbits weighing 0·64 ± 0·02 kg were given 250 mg calcium disodium versenate or 120 mg trisodium versenate once or twice a day In one instance 30 mg of trisodium versenate was given an hour before the calcium salt The older rabbits weighing 2·45 ± 0·12 kg were given 500–750 mg calcium disodium versenate once or twice a day Only one control rabbit given no versenate was included in each group since the figures both for excretion and retention agreed well with those obtained in earlier experiments (Kidman et al. 1950 Rayner et al 1953 Jowsey et al 1953) In one experiment the control was given an intraperitoneal injection of physiological saline twice daily since no effect on excretion was noted this was not done in other controls

Estimations of excretion and retention of ^{91}Y and ^{90}Sr–^{90}Y were made as previously described (Kidman et al 1950 Tutt Kidman Rayner and Vaughan 1952) The amount of ^{91}Y excreted is throughout expressed as the total over the period of examination Excretion in the fæces was small and unaffected by treatment it was therefore ignored after the first few experiments. Retention in skin, flesh, and each organ was initially determined separately but again the amount was so small that it was subsequently also ignored

Autoradiographs were prepared by methods previously described (Kidman et al. 1952) except that all sections were ground to the same thickness (200 μ) after cutting on the milling machine and were exposed for the same length of time on standardised X-ray stripping film specially prepared by Kodak Ltd This standardisation of the technique allows of comparison of intensity of reaction between autoradiographs.

Results

EXCRETION AND RETENTION OF ^{90}Sr–^{90}Y

Sodium versenate given 1 hour after a single injection of ^{90}Sr–^{90}Y equilibrium mixture and then daily for a total of 9 days.—These rabbits (aged 5–7 weeks) showed no reaction suggestive of tetany but on some occasions following injection they appeared rather collapsed for a few minutes: weight gain was not impaired The excretion of ^{90}Sr in the urine of the control animal was 15·0% of the injected dose compared with 13·2% in the rabbits receiving the versenate Retention in the

EFFECT OF VERSENATES ON PERCENTAGE EXCRETION AND RETENTION OF ^{90}Sr AND ^{91}Y IN RABBITS

Method of Administration	Young (5–7 weeks)				Old (12 months and over)			
	Control		Versene		Control		Versene	
	Urine	Bone	Urine	Bone	Urine	Bone	Urine	Bone
versene 1 hour after ^{90}Sr and daily for 9 days	15·0	50·0	13 2	60 8				
versene 1 hour after ^{91}Y and daily for 9 days	1[illegible] 3 ± 0 7	72 9 ± 2 9	53 3 ± 1 2	36 0 ± 1 8				
versene 1 hour after ^{91}Y followed by CaNa$_2$ rsene daily for 9 days	1[illegible] 3 ± 0 7	72 9 ± [illegible] 9	56·2	3[illegible] 8				
versene 1 hour after ^{91}Y and twice daily for days	1 3 ± 0 7	72 0 ± 2 9	61 5 ± 2 7	20 0 ± 1 8	25 5	59 5	75 [illegible]	21 3
versene 2 weeks after ^{91}Y for 4 days	20 1	62 7	32 7	52 2			33 [illegible]	45 [illegible]
versene 2 weeks after ^{91}Y for 12 days once daily	[illegible]1 8	6[illegible] 4	51 7	40 3				
versene 2 weeks after ^{91}Y for 12 days twice daily	19 0	77 2	58·0	3[illegible] ± 1·6	37·07	59 3	51 11 ± 1 8	47·0 ± 3 [illegible]

bones of the latter was 60 8 %, while in the control it was 50 9 % ^{90}Y excretion was increased by administration of versenate as shown by examination of the restoration of the equilibrium concentration of ^{90}Y in the urine (Kidman et al 1950, 1951) No quantitative results were obtained, for the counter wore out before its efficiency relative to the isotopes concerned was determined

EXCRETION AND RETENTION OF ^{91}Y

Rabbits Aged 5–7 Weeks

(*a*) *Calcium disodium versenate given 1 hour after a single injection of ^{91}Y and daily for 9 days*—The animals excreted a total of 58 3 ± 1 2 % of the injected dose while the controls excreted 12 3 ± 0 7 % The bones of the control contained 72 9 ± 2 9 %, compared with 36 0 ± 1 8 % in the treated animals, retention in the carcase apart from the bones was 8 0 % in the control and 2 7 ± 0 2 % in treated animals (fig 1, table) Two animals received daily 30 mg of sodium versenate, followed an hour later by calcium versenate The total ^{91}Y excreted was not increased compared with animals receiving calcium versenate alone

(*b*) *Calcium disodium versenate given 1 hour after a single injection of ^{91}Y and twice daily for 9 days*—The rabbits showed no toxic reaction and gained weight The mean total urinary excretion ^{91}Y was 61 5 ± 2 7 % compared with 12 3 ± 0 7 % in the control The mean total retention in the skeleton was 26 6 ± 1 8 % compared with 72 9 ± 2 9 % in the control (table, fig 1)

Geographical autoradiographs prepared from longitudinal sections of the tibia fibula (fig 2) show a generalised reduced reaction throughout the whole bone in animals which had received versene compared with the control The most noticeable difference was in the region of the lower end of the metaphyseal trabeculæ No reaction was present in the autoradiographs prepared from bones of versene-treated animals, while a heavy reaction was present in the control

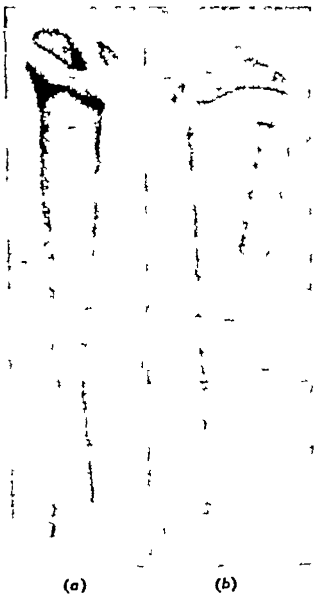


Fig 2—Geographical autoradiograph: longitudinal section of tibia of rabbit (5–7 weeks old) killed 9 days after a single injection of ^{91}Y (a) Control (b) Given an injection of versene one hour after ^{91}Y and twice daily for 9 days. Note (1) general reduction of reaction; (2) absence of reaction from metaphyseal trabeculæ.

(*c*) *Calcium disodium versenate given 14 days after a single injection of ^{91}Y each day for one period of 4 days Total period of collection 22 days*—There was a sharp increase in the daily ^{91}Y excretion in the urine after injection of versenate A total of 32 7 % of the injected dose was excreted by the treated rabbits, compared with 20 1 % by the control The skeletal retention was reduced from 62 7 % in the control to 52 2 % in treated rabbits (table, fig 1)

(*d*) *Calcium disodium versenate given 14 days after a single injection of ^{91}Y for a total of 12 days, divided into 4-day periods Total period of collection 38 days*—Each collection of urine after versenate injection showed an increased ^{91}Y content The total amount excreted was smaller in each successive The diminished response is only in part due decrease in ^{91}Y content of the bone (fig 5) total excreted was 51 7 % in the treated 24 8 % in the control, the total retained in the was 40 3 % in treated animals and 65 4 % in the (table, fig 1)

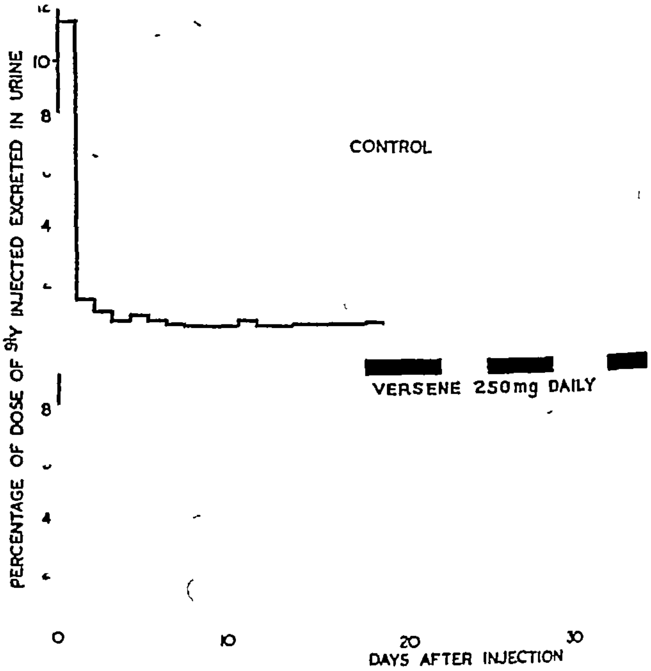

Fig 3—Average daily excretion of ^{91}Y in rabbits (5–7 weeks old) following inject

(*c*) *Calcium disodium versenate given 14 days single injection of ^{91}Y twice daily for a total of divided into 4-day periods Total period of 38 days*—The results were not greatly different those obtained in the series with single daily of versenate, although there was slightly more the urine The total urinary excretion was 5 the treated rabbits and 19 0 % in the control The skeletal retention was 35 2 ± 1 6 % in the treated and 77 2 % in the control (table)

Rabbits Aged 12 Months or Over

(*a*) *Calcium disodium versenate given 1 hour single injection of ^{91}Y twice daily for 9 days*—The total urinary excretion by the treated rabbi 75 2 % of the injected dose compared with 26 control, the skeletal ^{91}Y content was 24 3 % treated rabbits and 59 5 % in the control (table,

(*b*) *Calcium disodium versenate given 14 days single injection of ^{91}Y each day for 4 days Total of collection 38 days*—No rabbit was available to as a control in this experiment There was a increase in the urinary ^{91}Y output after inject versenate, but the increase was much less than case of the younger rabbits (fig 5)

(*c*) *Calcium disodium versenate given 14 days single injection of ^{91}Y for a total period of 12 day into 4-day periods Total period of collection 3*—The rabbits treated with versene excreted 51 1 ± 1 of the injected dose compared with an excret 37 1 % by the control, the skeletal content of 47 6 ± 3 4 % in the treated rabbits and 59 3 % control (table, fig 5)

In all animals injected with versene there adhesions and some inflammation of the abdominal In the animal receiving normal saline no such were seen.

Discussion

The experiments described suggest that disodium versenate is effective in increasing the

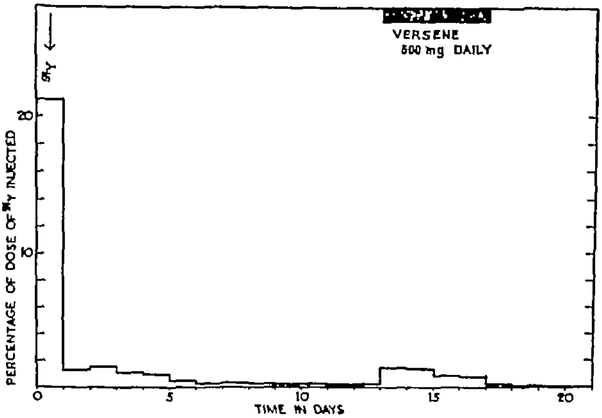

Fig 5—Average daily excretion of ^{91}Y in urine of rabbits (over 12 months old) following administration of versene.

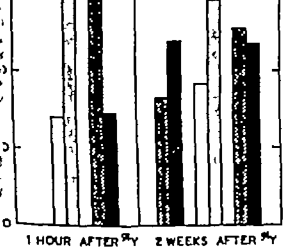
and ^{91}Y, especially in young s but is without effect on the ion of ^{89}Sr This is not sing Calcium excretion is sed by the administration of n versenate (Spencer et al. but the stability constants of rontium and calcium complexes ersene are not sufficiently nt to allow preferential com g of minute traces of stron n the presence of considerable ties of calcium (Cabell 1952) effect on yttrium excretion eater in young than in old ls. The skeletal burden is ciably reduced in both age s if the versene is given imme y after injection of yttrium f it is given two weeks later ffect in the older animals is These differences may be ined by assuming that chela ccurs with the yttrium present e blood-stream immediately injection or released to the -stream by the normal process orption The great reduction d in the lower end of the metaphyseal trabeculæ of g rabbits treated with versene for 9 days compared the control suggests that the isotope is removed areas of high metabolic activity associated with d blood-supply In old animals metabolic activity e bone is slight and little yttrium is released to the -stream. The skeletal burden is therefore not ciably reduced

is difficult to understand why the administration o doses instead of one in each 24 hours has little upon the total amount of yttrium excreted.

atever the mechanism of the increased excretion, suggested that the administration of calcium nate to young people who may inadvertently ingest active yttrium and possibly the rare earths, offers some hope of reducing the skeletal burden particularly if given within 24 hours In man it should probably be given by slow intravenous transfusion (Spencer et al 1952 Sidbury et al 1953) The correct dose is still a matter for investigation †



—Excretion and retention of ^{91}Y in rabbits (over months old) following daily administration of sene.

Summary

Experiments are described on the effect of injections of calcium disodium and trisodium ethylene diamine tetra acetic acid on the excretion of certain bone seeking radioactive isotopes in rabbits

The calcium disodium salt appears non toxic and has a considerable effect on the excretion of radioactive yttrium in both young and old animals if given shortly after injection of the isotope. If given 2 weeks after injection it reduces the skeletal burden in young rabbits but not appreciably in older animals It is without effect on the excretion of radioactive strontium

This chelating agent may well be of therapeutic value in people who ingest certain bone-seeking isotopes.

We should like to express our thanks to Prof J H. Burn, F.R.S., whose constant help and encouragement has made this work possible. We are grateful to the Bersworth Chemical Company for a generous gift of calcium versenate. One of us (J M. V) has an expenses grant from the Medical Research Council We are also indebted to the Hæmatological Research Fund endowed by the Nuffield Foundation.

tent experiments have shown that reducing the amount of ver e to 120 mg daily does not reduce excretion; reduction to mg daily reduces it to a moderate extent.

MALNUTRITION IN THE ELDERLY

H FULD
M D Heidelberg, M R C P
CONSULTING PHYSICIAN, NEWSHAM GENERAL AND SEFTON GENERAL HOSPITALS, LIVERPOOL

K V ROBINSON
M B Durh D P H, D C H
LATE MEDICAL REGISTRAR NEWSHAM GENERAL HOSPITAL, LIVERPOOL

MUCH has been written about the effects of widespread starvation associated with political strife, war, and the great famines due to failures of crops such as are still seen in China and India today This paper deals with less dramatic circumstances of malnutrition which are not uncommon in general and hospital practice even in these islands, and which mainly affect the elderly

In the first half of this century nutritional research concerned itself so successfully with infants and children that rickets and infantile scurvy have become almost historic diseases We intend in this paper to show that there are opportunities for investigation of malnutrition in the aged, and that there may be need for fresh means of solving social and medical problems which are likely to grow in proportion to the ever increasing span of life

Diagnostic Criteria

Most of our statements are based on case-histories of patients in a general hospital which admits, mainly, but not exclusively, the aged ill Only patients who were under the personal supervision of both or either of us have been considered in this review, which comprises 39 patients of both sexes Only those in whom malnutrition was the primary and main disability were included In a number of patients we believed that reactivation of fibrotic phthisis, development of non-specific respiratory infections, or urinary sepsis, were in fact secondary to malnutrition Such cases were, however, not included, neither, of course, were such conditions as pernicious anæmia or malignant disease associated with malnutrition

In the course of 17 months, from May, 1951, until September, 1952, 1 patient out of 36 non selected admissions to two medical blocks at Newsham General Hospital suffered from malnutrition The total number of admissions to these two blocks was 792 The rather high incidence of 2 8% showing malnutrition is explained by the fact that the hospital admits mainly the higher age groups No comparable figures are available from other hospitals

Diagnosis of malnutrition was based on a detailed history supported by interview with relations or friends of the patients in the hospital, and with the help of the hospital almoner in the patient s home, and a clinical examination with full use of radiological and laboratory investigations, and in some cases with consideration of the response to specific remedies like ascorbic acid or high protein diet

An effort was made to obtain detailed information about the financial status of the patient and cost of the essential items of the weekly budget with special reference to food costs Old people almost all suffer from several disabilities, and in that sense malnutrition was rarely the only disorder Arteriosclerosis, hypertension, emphysema, and arthritis were often associated with it, but had no evident relation to the type of nutritional deficiency, nor did they materially affect any therapeutic measures taken Many more cases of nutritional deficiency were treated by us than the 39 under review, but investigations before 1951 were often incomplete and it was not until we introduced a special case record chart for nutritional deficiency that we obtained comparable data

Age-distribution

There were 18 men and 21 women in our review Their ages were

35–40	1	65–70
41–45	1	71–75
46–50	2	76–80
51–55	2	81–85
56–60	0	86–90
61–65	7	

The fact that 33 of the 39 patients were over of age is significant, even in a hospital which itself mainly with the aged One of us (H F lected cases of nutritional deficiency in another hospital of comparable size which admits all a and he has found the same prevalence of m in the elderly Only quite exceptionally was as a primary disorder, found in the middle or groups The social and economic history of gives the answer to the peculiar age-distribution industrial city the aged are financially the least group It is said that "the first cause of hu malnutrition is poverty," and in fact 29 patients series admitted lack of money as the main cause nutrition On closer analysis, however, it was just lack of money but unfavourable living c loneliness, and the inability to spend money which brought about the state of malnutrition causes of nutritional deficiency other than conditions were physical handicaps such as arthritis of hip-joints, Parkinson's disease, str diet, indifferent cooking, anorexia, and food but together they represent only a quarter cases under review It appears, therefore, pert deal with the financial and social aspects of ol some detail

Economic Factors

Various surveys in the past fifty years have the close relation between poverty and old between poverty and malnutrition The needs," or subsistence, as distinct from the diet and its weekly costs at current prices have calculated in those surveys (Rowntree 1918, 1934, McGonigle and Kirby 1936, Schulz 1948, If, as Schulz (1950) found, a single person could just obtain an adequate diet on about 12*s* per 1950 this must have been even more difficult in since the index for food prices increased from June, 1950, to 150 in January, 1952, thus rais figure of 12*s* to 14*s* 6*d* In the analysis of the of malnutrition in our group, we blamed poverty weekly budget provided 12*s* or less for food. The larity of the diet taken by these people was strik the following sample was typical

Breakfast —Bread and butter or margarine, tea

Midday (usually the main meal) —Either meat (m brawn) or fish or one egg, on about three days a week, p boiled or chipped, bread and butter or margarine At ends a vegetable and meat stew would take the place above midday meal

Tea —Bread and butter or margarine, jam and tea

Supper —Cocoa or tea

Most patients drew their full ration entitlement w exception of meat, which was often refused becaus expense, brawn being taken instead Green veget usually cabbage—were bought once a week Citr other fruit was rarely eaten

In 31 of the patients, details of income and expend were obtained, though accurate and complete f were not available in every case

Total expenditure on food for a whole family was k for instance, but it was not possible to assess how m spent on feeding the old man or woman within the f In a few cases food expenses were known, but not th weekly income In others details of fixed expenses (rent and fuel) were readily obtained, but the patients uncertain about expenditure on food In 8 patients income was between 25*s* and 30*s*, in 5 it was betwe and 35*s*, in 4 it was between 36*s* and 40*s*, and 4 patients more than 41*s* to spend Expenses for food were figures by 26 The average weekly sum spent on food 2s 2d The average rent was 7s 2d for 31 patients tients knew their fuel costs, with an average of 5s 2d r was the average for light and gas for 9 patients Only nitted relative extravagance on alcohol and cigarettes rently high to cut their resources for food below the num need Another 3 had to pay high rents, leaving too money for food

31 patients, 15 did not admit to any additional rces besides old-age pension The remainder ed supplementary pensions from the National ance Board, from private employers or in the form men s pension in addition to the old-age pension is much to be said for the view that primary ty among the aged can be avoided under present tions, but it does require an approach to the National ance Board—a step which many old people seem stpone as long as possible

Symptoms

tailed history taking in malnourished old people is ie-consuming and trying task which explains why utrition or even frank starvation often remains spected before admission of the patient to hospital as to be expected, malignant disease of the gastro inal tract figured first among the provisional oses given by the general practitioner Œdema iated with starvation was generally attributed to stive cardiac failure or nephritis, and massive ing into subcutaneous tissues from scurvy simulated itis. Only in 3 patients in our group of 39 had utrition been recognised before admission

e duration of subnormal feeding was difficult to Memory difficulties of the elderly were aggravated he apathy due to malnutrition and in many cases id to rely on the statements of relatives and friends period of deficient food intake before hospital treat- varied between two months and eleven years, with rgest group giving two years as the length of time feeding

e symptoms which led to the request for medical e in the first instance were varied.

orexia was the leading symptom in 10 patients d not prove to be a manifestation of starvation as us as it is in younger people (Schwarz 1915) vo out of every three patients complained mainly of *ude*—a symptom far too usual among the aged ill ve any special significance in malnutrition

ight loss was the leading feature in 24 cases but not reliance can be placed on this figure quite often got unsatisfactory replies about weight loss. No parable figures are available as to how younger le could have fared as regards weight loss on diet which rather older people had taken for so

imentary upsets in the form of constipation were ally mentioned by 12 patients but only 3 complained arrhœa—a proportion very different from that seen ne of us (Fuld 1945) in concentration-camp victims ig the late war The conditions of mass starvation mps however are entirely different from those of group and the absence of diarrhœa in all but 3 of cases was probably due to the lack of enteric tions which accompany overcrowding

of our patients specially mentioned *difficulty in owing* Of the 8 women 6 had a profound microcytic nia while the man had only a mild normocytic mia. Dysphagia is common in elderly women with utrition accompanied by microcytic anæmia of e degree; we presume that we were dealing with the mer Vinson syndrome

of our group mentioned *distressed breathing* as one heir main complaints. Uncomplicated starvation is not to cause dyspnœa even after some physical ise In 6 patients of our series the dyspnœa was to profound anæmia with hæmoglobin levels of and below; in others cardiac and pulmonary ficiency were responsible

Difficulty in walking was noticed by 22 patients and the causes included arthritis arteriosclerotic vertigo hæmarthrosis of knee joints due to scurvy intermittent claudication, non articular rheumatism ulcers of legs and neuritis. Most of these patients also complained of pain in the legs.

Signs

Severe emaciation was observed in only 3 of our female patients whose appearance was not unlike that of Belsen victims Their recovery was complete but took up to seven months

Less drastic *weight loss* was found in all but 11 patients of whom 7 were grossly œdematous so that the actual loss of body tissues was masked. Concealment of tissue loss by fluid retention is often observed in the course of obesity treatment.

Some degree of *œdema* was present in 20 cases; a third of these had cardiac insufficiency adequate to explain fluid retention on that basis alone Of the remainder 8 were grossly anæmic, and had scurvy or a low plasma protein Gross nutritional œdema affecting the whole body associated with ascites and pleural fluid such as was seen in concentration-camp victims was only observed in 1 of our male middle aged patients whose plasma protein on the third day of hospital stay was just over 5 g per 100 ml and who had lived on a diet free of water-soluble vitamins for several months Three injections of 100 mg vitamin B_1 on successive days caused a massive diuresis and completely cleared the fluid retention Patients with renal œdema were omitted from our list

Some degree of *vitamin A deficiency* would have been expected in our patients if one accepts the data of the commission of the League of Nations which in 1937 decided that an adult requires about 3000 international units of vitamin A daily This amount is present in about 3½ oz. margarine or 1¾ oz. butter or 2 pints of milk which is considerably more than the daily intake of most of our patients An adult only absorbs 25% of carotene from carrots or spinach—vegetables which were rarely taken by any of our patients. Xerophthalmia was not observed in our group No dark adaptation tests were carried out 12 patients showed hyperkeratosis of the outer aspects of thighs and legs, but in the absence of estimations of the plasma level of vitamin A we felt these changes could not with any certainty be attributed to vitamin A deficiency particularly as similar skin changes can be produced by deficiency of the vitamin B complex by vitamin-C deficiency and by senile atrophy of the skin

Only 1 of the patients under review to whom we have referred also showed clinical signs of *thiamine deficiency* The therapeutic dose with injection of vitamin B_1 at the onset of treatment when the patient had received no other form of therapy resulted in massive diuresis and cessation of diarrhœa

10 patients suffered from angular stomatitis or cheilosis There were in addition 13 who had glossitis alone 3 cases of long-standing diarrhœa and 1 male patient with diarrhœa and dementia which cleared up under treatment with compound vitamin B tablets. Almost all our patients were living on a diet grossly deficient of the chief sources of *vitamin B_2* particularly of fresh green leaves, liver kidney or pork

It is recognised that acute and complete starvation is rarely associated with vitamin deficiency Bruckner et al (1938) suggested that this is due to liberation of the required vitamins from tissue breakdown which would explain the experience that vitamin deficiencies are more prevalent in starvation not accompanied by severe weight loss Our patients suffered from semistarvation and it is in these cases that the type of food available determines the type of vitamin deficiency which is likely to develop The problem is difficult however as vitamin-deficiency symptoms such as keratomalacia follicular hyperkeratosis and œdema may be ascribed to the semi starvation itself rather than to a specific vitamin deficiency In doubtful cases we have been guided in the diagnosis by the effects of large doses of a specific vitamin given by injection We assumed for instance that disappearance of glossitis and angular stomatitis within a few days after intramuscular injections with large doses of the vitamin B complex can be of diagnostic value

The diagnosis of clinical *scurvy* was far less dubious than that of vitamin-B deficiency We saw 19 cases of scurvy, the clinical criteria being

1 History of gross dietary deficiency in fruit and fresh vegetables

2 Presence of hæmorrhages in skin, subcutaneous tissue, and joints, and swelling of the gums (absent in edentulous patients)

3 Positive Hess test

4 Significant results with ascorbic acid saturation tests (not carried out in all patients)

All but 2 of our scurvy patients were anæmic to a greater or lesser degree, 7 had a normocytic anæmia and the blood films of the other 9 showed microcytosis and hypochromia In 2 patients the anæmia was macrocytic on admission but became normocytic under treatment with ascorbic acid, as described by Parsons (1938) 17 patients developed scurvy because they could not afford vegetables and fruit One had adhered to a strict ulcer diet, and another was mentally deranged and unfit to cater for herself

We have not observed in our group a single case of malnutrition with clinical evidence of *vitamin-D deficiency* Nor have we seen the hunger osteopathy described in Holland after the Liberation

The *skin* of most of our patients was dry, loose, scaly, and atrophic—changes which recur in most reports from famines In our group with its high age-level no special significance has been attributed to these changes, which could be due to senile atrophy alone without malnutrition We were, however, struck with the high incidence of *pigmentation*, shown by more than a quarter of the patients This was general and not localised to the exposed parts One extreme case suggested Negro origin, which was not borne out by an interview with relations it was in fact a severe case of "melanodermia of vagabonds" in a heavily-infested starved woman whose home conditions were indescribable Some degree of skin pigmentation in most victims of starvation has been reported by one of us (Fuld 1945) from Belsen camp We believe that at least three factors were responsible for the pigmentation in our group—infestation, starvation, and possibly nicotinic-acid deficiency Pigmentation faded with improvement of the general condition

The *dental state* in 21 of our patients was deplorable, the remaining 18 were edentulous, dental caries was present in 14, the other 2 had pyorrhœa and loose teeth. It is often said that bad nutrition results in an increased incidence of dental caries, and that dietary improvement should reduce the tendency of teeth to decay There is no support for this view from field experiences during the late war, from reports from famine areas, or from controlled experiments The history of our patients suggested that their poor dental state was the effect of life-long neglect

Notes were made on the *mental state* of the 39 patients on admission to hospital The behaviour and outlook of 28 corresponded to the average expected in patients of their age-group and social environment, 11 showed definite changes, with apathy and an attitude of hopelessness in 9, and anxiety and agitation in 2 "Primary" senile dementia cases were omitted from this series The progress made during treatment, and the disappearance of mental aberration, suggested that the psychological changes were at least partly due to malnutrition, which had affected the whole organism including the mental functions

How far malnutrition as such can be blamed for mental changes cannot be assessed The relentlessly depressing effect of poverty, dirt and cold—but particularly of loneliness—over a period of years is in itself sufficient to cause personality changes, but it seemed to us that the profound state of apathy was a direct effect of malnutrition Some seriously ill patients in advanced states of semistarvation presented a typical appearance, identical with that seen among prisoners at the Belsen camp They lay curled up on their sides and were entirely unconcerned about activities in the ward, but often resented any interference, such as washing or examination Bladder and rectal incontinence almost invariably present during the first admission, and feeding was difficult at this often resented One may speculate about the of physical lesions in the central nervous system and resulting mental changes, but the tissue of the are more resistant to morphological changes than those of any other organs No post- examinations of the C N S were carried out in the few of our patients suffering from extreme who died within a few days after admission

Malnutrition and Gastric Secretion

Gastric secretion was tested in all our patients 3 who refused permission We were interested effects of malnutrition on gastric acidity and its to anæmia Our experience of normal or average of gastric acidity in the elderly was limited, since seldom arises for carrying out fractional test old people, except for the differential diagnosis of and for suspected malignant disease of the We have, however, records of fractional test a number of elderly patients who were clinically of digestive disorders, blood-diseases, and defects Of the 26 males above the age of six (58%) had a histamine-fast achlorhydria, while 42 females above that age, 26 (62%) had a absence of hydrochloric acid

In our malnutrition series 36 patients were fractional test meal within a few days of 27 (70%) had a histamine fast achlorhydria, 1 acid secretion, 5 showed excessive values for free hydrochloric acid, and 3 secreted normal Of these 36, 27 were re-examined by gastric at the end of their treatment At that time 7 patients initial achlorhydria had recovered their gastric 5 of them showing a normal acidity curve, 1 chlorhydria, and 1 hypochlorhydria The re after clinical recovery, still had achlorhydria. gained the impression that malnutrition contributes towards achlorhydria, and that treatment of malnutrition tends to restore secretion in some patients As a result, the inci achlorhydria in the recovered patients resembl which we found in our control series of people of the age group

Malnutrition and Anæmia

Apperley (1936) believed in a direct relation *red-cell count* of the blood *and gastric acidity* that a fall of the red cell count to half or two- normal is followed by disappearance of free hy acid in the gastric secretion He distinguishes between the achlorhydric anæmia of Witts and achlorhydria We could not confirm his obser 4 of our patients had a blood count of less than normal, but showed average gastric secretion in test-meals

All but 3 of our patients were anæmic to a varying from 80 to 25% hæmoglobin, with red as low as 2 million per c mm The anæmia was cytic in 12 patients, microcytic in 20, and macro Of the macrocytic anæmia cases, 2 had low protein on admission and had lived on tea, bread, jam After treatment, which included a high diet, but excluded folic acid, liver, and vitamin anæmia cleared up and the blood became Achlorhydria was converted into normal gastric in 1 of these cases

The third patient with macrocytic anæmia, aged admitted in a condition of extreme neglect She had several months on a diet which excluded any green veg on very rare occasions she took first-class protein in n or bacon Her anæmia was hyperchromic on admission million red cells, 60% hæmoglobin colour index 1 2) bone marrow count did not suggest pernicious anæmia nade a full recovery on a high protein diet reinforced by ins. This patient's condition was reviewed six and o months after her hospital treatment and although she recovered from her anæmia the colour index remained 1·0 On the last count she had 4 million red cells, 115% oglobin and colour index of 1 5

Treatment and its Effects

o treatment of complete and partial starvation in lderly did not present any special problems Only patients arrived at hospital in a state of starvation were that they could neither swallow nor digest le foods They were treated initially by skimmed drips through a Ryle's tube After two days on a régime they were able to swallow foods. The early bilitation diet was of low bulk in all patients, and lly consisted in skimmed milk reinforced by Casilan o) Compound vitamin B tablets 6 daily, with rbic acid 200 mg, were added There was rarely need for vitamin injections Iron was given orally ore often by intravenous injection In the great rity of our patients, simple foods taken by mouth all quantities frequently were well tolerated within or three days. Thereafter the nutritional rules which y to feeding in childhood were followed until such as the patients could digest and assimilate ordinary ital diet, distributed in four meals a day There no relation between gastric secretion and appetite r cases. Although most of them had achlorhydria he onset of treatment we found no indication for ribing hydrochloric acid. Given the chance most people tend to eat more than they need, and our nts ate surprisingly well after a very short period of bilitation. They kept on eating somewhat excessively after they had fully recovered

eight Gain—The value of gain in body weight is ult to assess. Fat deposits tend to increase at a r rate than that of active tissues, and changes in body ution are a complicating factor It is, nevertheless of the indices of nutritional rehabilitation Of 17 nts, 13 gained an average of 10 lb with a range of lb, 6 gaining more than 1 st Of the remainder 1 ved no change, and 3 lost an average of 4½ lb the er initial weight being due to fluid retention

he results in this series of 30 cases did not entirely esent our experience during the last seven years have treated a far larger number than the series rted here, but have omitted them because of lack ertain investigations or adequate follow up or on unt of associated diseases which had some major ence on the patient's condition. During the earlier s, at the time when the present wide range of biotics was not available we lost patients in an anced stage of starvation from sudden heart-failure from intercurrent infection In the present series lost only 1 patient, who developed an intractable rhœa

uration of Hospital Stay—The minimum time of for patients with nutritional deficiencies was three ks. Some advanced cases of starvation in the aged ired up to nine months for full rehabilitation Wide-ad pigmentation in long-standing cases of mal rition may take up to twelve months to clear More n than not hospital care had to be extended well ond the period required for physical recovery There o group of patients in whom social problems play a er part in the ætiology of the condition or in the isposal at the end of treatment. Many of them had homes to return to and neither relatives nor friends accept their care Some were eventually accommo-ed in municipal institutions and charitable homes re remained a group which refused to enter such itutions and therefore had to remain under the roof he hospital

Follow up

Patients were followed up after discharge either at the hospital or at home Specific questions were put to 12 patients, selected at random for visits in their homes by staff attached to the Medical Officer of Health's department in Liverpool We were interested to know whether the patients had seen their doctors (who had received full reports from us); and comparisons were made between diet after hospital discharge with the conditions before admission Details of the diet with supplements like vitamins and iron were recorded as accurately as possible Living conditions were compared with the pre hospital period and the investigator tried to find out from the patients whether they had in fact realised that under nourishment was the cause of their ill health.

The result of this small-scale inquiry was disappointing Of the 12 patients only 8 had visited their doctor at home or had called him in. Only 4 had improved on their diet and 2 more had kept well by taking vitamin C tablets for scurvy which was their original disability The living conditions of the 4 patients who were taking an adequate diet had materially improved.

CASE 1—Mrs. A, previously under the care of a landlady who is alleged to have given her short rations Now living with sister who looks after her well Her actual financial position is unchanged

CASE 2—Mrs B wife of a regular soldier living with 3 children She had been starving herself to feed the children and was admitted with an iron-deficiency anæmia (Hb 25%) She had been advised on diet by her own doctor and claimed to be eating more than before admission to hospital

CASE 3—Mr C lived alone in an old age pensioner's flat preparing his own meals. Now living with a son and daughter in law No actual change in financial position

CASE 4—Mrs D a widow still living with her son to whom the mother's condition was explained, and who had persuaded her to eat more No change in financial position.

All but 1 of the patients whose living conditions were improved had consulted their doctor Of the failures only 3 had visited their doctor since discharge. Adverse reports on personality and living conditions were made by the investigators in 5 of the 6 relapsed cases, of whom only 1 supplemented the deficient diet by vitamins and iron Of these 6 patients who had gone back to the sub normal standard of feeding 1 had returned to his common lodging house taking his meals outside (carbohydrates and tea) 1 refused any food containing fat and had lost 11 lb in weight since discharge and 1 had no cooking facilities except an open fire. In only 2 of the relapsed cases was lack of money the only factor

Prevention

Hospital treatment of malnutrition in the aged is long and expensive and—quite apart from humanitarian considerations—this should make us prefer prevention Inadequate feeding unsatisfactory housing loneliness, and hopelessness are the main factors which eventually bring the patients to hospital. Ideally they should have been dealt with at the source Yet only a small pro portion of people in this country know about the incidence of malnutrition in the elderly and its social implication

To quote David Lloyd George How we treat our old people is a crucial test of our national quality'

Care for the aged is, of course, primarily a family affair The duties involved, which usually fall upon a daughter or daughter in law are uncongenial. The problem is aggravated by the frequent necessity for the woman in the household to go out to work to supplement the family income For obvious reasons it is desirable that old people without a family should occupy the ground floor flats of tenement buildings or an old people's hostel in a housing estate with arrangements for com munal cooking and general supervision by a matron Until these ideal conditions prevail, we suggest that malnutrition and starvation cases be notified by the general practitioner to the medical officer of health, so that health visitors may investigate the social conditions of each case and report their findings to the hospital if admission is deemed necessary The health visitors should also be notified on the patient's discharge from hospital so that they can supervise him at home Iron tablets and vitamin compounds could be supplied to the elderly on the same principle as cod-liver oil is freely supplied to children

Lord Beveridge wrote "It is dangerous to be in any way lavish to old age until adequate provision has been assured for all other vital needs such as prevention of disease and the adequate nutrition of the young" But this was written in the pre penicillin days of 1942 when pneumonia still sealed the fate of many old people in the winter months of each year Since then changes in the age distribution of the population have been brought about to a great extent by the introduction of antibiotics, while adequate nutrition of the young has been assured and preventive measures against infectious disease in childhood had a great measure of success The conditions of Lord Beveridge's statement of ten years ago are therefore fulfilled, and the time has come to consider more closely the welfare of the aged population by directing preventive measures towards those over sixty These measures should include suitable housing accommodation for the lonely aged, arrangements for communal feeding and settlements for the aged, or "meals on wheels", vitamins and iron supplements through clinics, or through practitioners, to those in need, and regular visits by welfare workers to lonely elderly who have a record of medical attention for malnutrition

Summary

Even today, grave malnutrition in the elderly is not uncommon and often goes unrecognised.

A series of 39 cases seen at one hospital during seventeen months is described, with observations on the effect of starvation on the mental state in old age

The results of test meals in 36 of the patients suggested that malnutrition increases the incidence of achlorhydria in the aged In some cases, but not in others, the achlorhydria was reversed by treatment We have found no relation between achlorhydria and the degree of anæmia

Most of our patients had a microcytic or normocytic anæmia, only 3 had macrocytic anæmias

Response to treatment was generally good, but sometimes slow, and for social reasons the patients often had to be kept in hospital well beyond the period required for physical recovery After discharge from hospital many of the patients unfortunately returned to the diets or conditions which had caused them to starve

Prevention of malnutrition in the elderly will require combined action in the social and medical spheres For this reason notification of cases of starvation to the medical officer of health's department is suggested

We wish to thank Dr A B Semple, medical officer of health for Liverpool, and his staff for their coöperation in the follow up of our patients, and Dr J Carr Brundret, Dr F H Moorhouse, and Dr R Y Dawbarn for their ready help in pathological investigations and their advice

INCISION FOR ACUTE APPEN

M R Ewing A K
M B Edin, F R C S, F R C S E M.D Camb
SENIOR LECTURER LECT

DEPARTMENT OF SURGERY, POSTGRADUATE ME
OF LONDON

The frequency with which the acute
approached, in this country, through a
paramedian incision must result from th
teaching in our medical schools of these a
choice They certainly have the sanction
the standard works on operative surgery
that these incisions should be discouraged in t
of the acutely inflamed appendix

The acute appendix has, of course, been
removed from the right iliac fossa through
incisions, ranging from the midline epigastri
groin incision for hernia This is no indicati
for their general adoption in the treatment o
which is responsible every year in Englan
for 1200 deaths as well as for a considerable

The ideal incision should give the most
to the appendix, with the minimum of
and retraction both of the parietes and of th
contents, it should involve the least openin
planes in the abdominal wall which may
sequent infection, for the difficult case,
safely extensible in either direction witho
nerves, it is helpful if drainage can be
established through it, it should be condu
rising without increased risk of hernia form
the risk of subsequent herniation should be
if a hernia does occur it should lend itself
sound repair

How do the incisions in common use fulfil th

INCISIONS IN RIGHT ILIAC FOSSA

The *muscle-splitting incision* gives a sligh
line of approach to the appendix, erring o
or flank aspect This is a good fault,
that it involves less disturbance to the gener
contents Not necessarily where McBurney
described it, but intelligently placed at
lower level according to the physical signs,
affords fair access If the exposure is limited,
can be safely extended laterally by cutting
oblique and transversus muscles, or mediall
the rectus sheath Being valvular it is quick
closed, is strong from the outset, and f
rising The risk of subsequent herniation is
should such a hernia occur it can be repai
excellent chance of success

The *muscle cutting incision* gives slightly
to the appendix with less retraction
bleeding ensues, however, it is more time-c
the making It lies parallel to the line of
nerves, which should therefore not be liabl
Whether they are in fact so immune in se
incision is a matter of opinion It has bee
that their inclusion in sutures during the cl
wound is responsible for the diffuse bulge
end of the scar which is seen from time to
incision is good for drainage and reasonab
early rising, the risk of hernia is not gre
results of repair are satisfactory

When appendicectomy is likely to be dif
an obese patient who has had previous att
diagnosed late, or when operating facilities an
are not perfect, a muscle cutting incision is to b
In so far as it cuts rather than separates
in the presence of likely infection it does
to the abdominal wall than does the mus

after *These disadvantages are, however in the* ult case more than outweighed by the better access h it affords, allowing the appendix to be removed less deep retraction, less handling of the bowel and peritoneal soiling

BATTLE S INCISION

eing placed closest to the surface marking of the of the appendix Battle s incision gives the most t access to it It is valvular and favourable for early lisation. On the other hand it opens up the rectus th widely involves considerable retraction, and ot be safely extended in either direction for fear njury to the 11th or 12th thoracic nerves In the ult case where extension of the incision has been ssary the risk of subsequent hernia is considerable uld such a hernia occur its repair is neither easy by any means always successful. In first describing incision for the removal of a non urgent appendix le (1895) stated that its advantage lay in the inter tion of the rectus muscle between the two parts of incision which would prevent the development of a a If drainage is used, the drain prevents this position of the rectus and therefore robs the incision s chief merit.

view of these disadvantages we maintain that le s incision has no place in the treatment of the e appendix

MIDLINE AND PARAMEDIAN INCISIONS

ese incisions have the support of tradition they have undoubted advantage in the treatment of the ult *pelvic appendix moreover* it is claimed for that if the diagnosis is incorrect, other lesions can ealt with conveniently through the same incision

s regards tradition the position should be carefully wed as regards other lesions such incisions ld not be used as a cloak for slovenly diagnosis, the excuse that the incision is the same in any The disadvantages of these incisions are formidable have hitherto been too little emphasised To the ndix in the right iliac fossa they give an oblique oach from the inner side across the general peritoneal ty *Handling and retraction of the lower ileum are* tial interfering with the natural process of locali on and favouring the development of immediate onitis and ileus as well as of subsequent adhesions. y rising is contra indicated because the abdominal cles in contracting pull away from the wound ly, but by no means least, the risk of incisional ia is probably greater than with any other abdominal sion. Further such a hernia is notoriously difficult ure and has not infrequently led to lifelong invalidism.

CASE RECORD

boy aged 10 years, was awoken at night by lower minal pain he vomited once When he was seen by octor next morning the pain had gone and he was n a bottle of medicine Four days later he was admitted ospital urgently with symptoms and signs of acute intesti obstruction including well marked ladder pattern visible stalsis Its cause was obscure

ration —After aspiration of the stomach and an intra us infusion the abdomen was opened through a right r paramedian incision Coils of distended ileum escaped the incision and after much retraction and handling he bowel foul smelling pus escaped from an abscess round ngrenous appendix lying over the brim of the pelvis on right side The appendix was removed and the wound d with drainage through its lower end Discharge inued for 2½ weeks, and the wound became infected. ncisional hernia developed throughout the length of the nd with 1¾ inches separation of the recti

admission.—Nine weeks later the patient was readmitted subacute intestinal obstruction a large tense coil of stine being palpable under the scar The condition did subside with medical treatment and laparotomy was *again necessary The boy is now left with a large incisional hernia He is a keen footballer and wishes to know when he may start playing again*

It was very much regretted that a muscle-splitting incision was not used in this case

CONCLUSIONS

In all cases in which acute appendicitis is diagnosed a muscle splitting incision should be made in the position suggested by the physical signs If removal of the appendix is difficult the incision should be prolonged by converting it into a muscle-cutting incision

If the diagnosis is uncertain but acute appendicitis is a possibility the first approach should be through a muscle-splitting incision. If the appendix proves to be the source of the trouble much has been gained. If the appendix is healthy and the cause of the condition cannot be readily dealt with from this approach a second incision is made in the appropriate place

A second incision may be an unpleasant surprise for the patient and is something of a blow to the surgeon s pride but it is of no significance when compared with the morbidity, both early and late which may follow the unwise removal of a gangrenous appendix through a median incision

MANCHESTER MEDICAL SOCIETY

Transfusion Problems

IN the section of pathology on Oct 14 Dr J F WILKINSON said that though the transfusion of blood and blood products often saved life it could also be wasteful unnecessary and even dangerous The decision to transfuse a patient and the type and quantity of the product to be used (whole blood, packed cells, blood fractions or substitutes) was the responsibility of the clinician, who alone could decide from a study of all the clinical and pathological features of the case

Dr F STRATTON, director of the North West Regional Blood Transfusion Service, observed that at the Manchester Royal Infirmary the reaction rate from transfusions was about 2 8% Assuming that the blood was correctly matched reactions were due to any of four factors pyrogens, which could be present in chemicals or arise from bacterial growth in distilled water too rapid transfusion ; the administration of small quantities of air which could be avoided by careful filling of the distal tubing of the giving set or sensitivity to plasma which was found in the recently delivered woman or where there had been abortion Such reactions could be avoided by giving *the blood slowly* in a carefully estimated amount by warming the patient (never the blood) and finally by a careful cross match, including a saline agglutination and Coombs test for incomplete antibody using a serum which was both potent and specific

Dr R F JENNISON speaking as a hospital pathologist responsible for the operation of a blood bank said that the refrigerator in which blood was kept must be locked only specified persons should be allowed to take blood from it all such removals being recorded and signed in a book. *The messenger taking blood to the wards should* produce a written slip to avoid mistakes in identity while any resident staff who were not attached to the pathology department and who might have to cross match blood at night should be examined by the pathologist to make sure that they were competent to make the necessary tests

Dr R W FAIRBROTHER said that some recent transfusion disasters had been due to gross carelessness

Clinicians often left the decision about transfusion to the most junior member of the team, and even to the sister in charge of the case During the past twelve months there had been two fatal accidents caused by nurses taking blood out of the refrigerator and connecting it up to the drip The surgeon should not ignore his responsibility in transfusion matters

Reviews of Books

Modern Treatment

A Guide for General Practice. Editors AUSTIN SMITH, M.D , editor of the *Journal of the American Medical Association* , PAUL L WERMER, M D , secretary, committee on research, American Medical Association London Cassell 1953 Pp 1146 £7 7s

THIS important book carries the weight of authority of 58 American authors of high standing, and is clearly the result of much labour and care Whether it will in fact, as the editors hope, provide a new kind of aid for general practice is less certain How best to provide help in a rapidly changing therapeutic era is still an open question and this book has not necessarily found the ideal method For the practitioner clear and precise advice is often needed , yet in many forms of treatment this is just what it may be impossible to give General principles may not be enough, and to omit some subjects or aspects of a problem because they are not solved or are still under investigation is more cautious than helpful

Nonetheless the book provides a vast amount of shrewd, balanced, and helpful information It is surprisingly up to date and for the most part simple and easy to read It is much more than a mere index of therapeutic agents and methods it is almost a complete textbook of medicine in itself and includes much that is not directly concerned with treatment Thus ætiology and diagnosis are included and there are separate chapters on laboratory methods of investigation, diagnostic radiology, and such subjects as the general principles of infection, the patient-physician relationship, and clinical immunology The chapters on psychosomatic medicine and geriatrics are particularly good There are no illustrations but the printing is beautifully clear and it is easy to see why the book costs seven guineas

The Ship Captain's Medical Guide

19th ed Ministry of Transport Editor M T MORGAN, M.C , M D , medical officer of health, Port of London H.M Stationery Office 1953 Pp 337 21s

THE price and size of the new edition of this venerable publication, once a slim pocket volume, may induce some ancient mariners to list it as an added peril of the sea But for all that it is a magnificent compilation on art paper in royal octavo with well-chosen diagrams and illustrations, many in colour

The contents range from bug destruction to bubonic plague, from ant-bites to the Archbishop of Canterbury (p 299) The whole is a gallant attempt to present to a layman of proved intelligence a précis of the more practical parts of the six year medical curriculum Added to this are 104 pages on first-aid and 25 on general nursing The authors have made the book readable despite its intense compression, and even a specialist will learn something fresh from the 8 pages on malaria or from the section on the venereal diseases It is not their fault that the antibiotics section is already out of date, though even last year few of us would have advised a 28 day course of penicillin injections The absolute restriction of chloramphenicol to cases of suspected typhoid fever also seems strange There could be little risk and possibly great benefit in trying a short course of this drug in lethal conditions when penicillin has obviously failed True to form, the fashion in artificial respiration methods has again changed Official blessing is now given to the Holger Nielsen arm lift back pressure method and a 5 page appendix with illustrations describing the technique is cunningly housed in a special pocket together with a further 56 page brochure entitled Medical Scales

At a conservative estimate, this volume should provide bedside reading to the conscientious ship's master for at least three return voyages to Australia

Adrenal Cortex

Transactions of the Fourth Conference, Novembe Editor ELAINE P RALLI, M.D , associate medicine, New York University New York Macy, Jr , Foundation 1953 Pp 165 $4 00

THIS account of the latest Macy conference o adrenal cortex gives an impressive picture of the and complexity of contemporary research into significance of the adrenal cortical hormones in and disease

The preoccupation of the conference members with purely experimental work (mainly biological and emphasises how slender still is the pharmacological which the therapeutic applications of the adrenal stero Of the four main discussion topics only one—adrena in man—falls into the clinical category Two long are devoted to the concept of the " permissive actio adrenal corticoids, and to the mechanisms through adrenal cortex can produce qualitatively different Although the argument is well sustained, and the Professor Selye's exposition gives much pleasure reading, the general reader may find this difficult stuf perhaps unrewarding The most useful section is that existence and nature of the salt-retaining hormone (" cortin ") detected by the Middlesex Hospital workers recently crystallised by Professor Reichstein. Dr Vogt's account of this steroid, and the discussion will be helpful to many now attempting to keep advances in adrenal physiology

A Study of Hæmoglobin Values in New South

R J WALSH, BARBARA J ARNOLD, H O La MARGARET A COOTE, HELEN COTTER. National and Medical Research Council Special Report no 5 Canberra 1953 Pp 84

THIS monograph supplements the surveys of globin values carried out in this country, the and elsewhere The photoelectric instrument fully described, as are the precautions taken to accuracy The results, which are well set out generally similar to those obtained in other It is interesting to note that in New South Wales the public servants, bank officers, and shop as who have the reddest blood the Armed Forces sh lowest mean hæmoglobin of the occupational tested Values in pregnancy remind us of the fall in hæmoglobin—from a maximum average of 1 per 100 ml to a minimum average of 12 10 g the 28th and the 32nd week. Diurnal variati considered and found not to be very important, at 1 P.M tend to be a little lower than average. authors support the opinion that the ear is the site for taking blood, and the vein the best. The on variations in childhood are useful, and an inter diagram shows the total hæmoglobin in grammes to the body during the years of growth , in the most is added in the 14th year, in the female in th year

Natural History of Infectious Disease (2nd Cambridge University Press 1953 Pp 356 22s 6 The second edition of Sir Macfarlane Burnet's book, already has achieved a unique place among works on in diseases, is relatively unchanged There are 40 more, some new illustrations, a new chapter on chemotherap some rewriting of some of the older chapters Considera great changes in the incidence of infection and in the practice it may seem surprising that more alteration been necessary thirteen years after the first edition, this is a book about the biology of infection, and much we rank as revolutionary—including the introduction antibiotics—is too recent for the full impact on disease to have been felt Control of vector borne and immunisation against such diseases as diphtheria yellow fever, have had much more rapid biological The author considers that the mid point of the 20th may come to be seen as the period when it became cl infectious diseases could be virtually eliminated The for the future, as he sees it, depends much more upo threat to use microbiology as a weapon of war tha Nature

THE LANCET

LONDON SATURDAY OCT 24 1953

Truth from Statistics

HE W H O *conference on medical statistics*, held ondon last week[1] differed from many other inter onal gatherings of this sort by arriving at a firm constructive conclusion the delegates acclaimed concept of national committees composed of rested people from government and medicine ed by a W H O central unit and refreshed by ılar international conferences The intention is these should act as a statistical conscience *ulating and training people to do fresh work* ing rid of useless routine tabulations and publi ıg the value of statistical research The means to end were the main topic of discussion

he conference crystallised the notion that sampling edures are often cheaper, quicker, and better than arently complete collections of vital-statistical ı In the technically advanced countries, where stration of births and deaths is essential to the oth *working of systems of social security*, this is ted completely and reliably In no country ever is the cause of death always recorded arately—the registered causes of death from more n one disorder in older people are particularly open question—and in some countries the certifying sician may be influenced by the legal and psycho al consequences of certifying certain causes This culty can be overcome by necropsy or other special uiry in a *small but representative sample* Then n, the results of a decennial census may be affected movements of people from job to job or place to o *and thus calls for repeated sampling surveys* he occupational and geographical distribution of population. Sampling may be valuable too, in lies of morbidity no regulations demanding the fication of all cases of even a few non infectious ases would be fully obeyed but much could be nt from detailed reports of a small random sample nterested general practitioners Likewise in the nically less advanced countries where registration births and deaths is incomplete trends in fertility mortality can be discerned from the carefully rded *experience of small areas chosen to represent* ections of the country in such areas the preva o of sickness of all kinds can best be ascertained n intensive studies by mobile medical survey teams eed, whatever the need sampling can give answers kly, accurately, and cheaply Although the cost subject may be higher than in a complete survey total cost measured in terms of useful information, much smaller, and if time is indeed money the ld tabulation from a sample survey represents a hor saving At first sight it would seem unrealistic use sampling methods to check the accuracy of a nplete registration, but when for example some % of disabling illnesses are assigned to no clearly defined cause *the only possible way to learn more* is to investigate a representative sample and to generalise from the results thus obtained

Without trained staff all this would be out of the question, and the conference made parallel recommendations on training The United Nations central statistical organisation is producing instruction manuals, and the exchange between different countries of coding details and other training material should *ensure accuracy and uniformity in classification* Furthermore, the epidemiological and statistical section of W H O is being encouraged to attune training methods to the public health requirements of member countries These and other measures, such as special courses and fellowships will help to meet the need for lay ' health statisticians ' and for medical specialists in preventive medicine to interpret and use the results obtained The main problem now *rests with our own profession* Unless *the general* practitioner is convinced that certification has a clearly useful object he is not going to give it the conscientious attention it demands he must see that the data he provides are used quickly and effectively by other medical men—locally nationally and internationally It is his interest that the national committees must strive to seize and sustain

Coarctation of the Aorta

ANATOMISTS have recognised aortic coarctation for two hundred years Yet less than thirty years ago a cardiologist declared that ' the diagnosis is rarely made during life "[1], and it was only after the publication in 1933 of accounts by LEWIS[2] and EVANS[3] that *this situation was changed* *Coarctation of the aorta* is a very serious abnormality A few patients with it reach old age but without surgical treatment many die in infancy and of those who reach the age of 17 more than half die before the age of 34 The remarkable advances in vascular surgery[4] have however entirely changed the outlook

The cause of the defect is unknown, but it has been found in embryos and is probably a true error of development unconnected with the closure of the ductus arteriosus Its prevalence is difficult to assess, but it must be lower than the necropsy figure of 1 in 2000, *and obviously it is higher than the 1 in 80,000* estimated from mass-radiography examinations A useful distinction may be made between (*a*) the so called infantile type, where the defect is usually severe (sometimes amounting to atresia of the aorta) and is often accompanied by other congenital defects in the cardiovascular system and elsewhere, and (*b*) the adult type where the narrowing is less severe With this type there is commonly no other serious abnormality, but in 25% of cases there is a bicuspid aortic valve, and the prevalence of berry aneurysms at the base of the brain is undoubtedly higher than the average In some cases, too the ductus arteriosus remains patent In the adult type the constriction *varies from an annular stenosis to a narrowed segment* several centimetres long The constriction is usually *just below the opening of the ductus* but *may* be at or above this level or occasionally in the lower dorsal[5] or abdominal aorta With the stenosis there is often kinking and distortion of the proximal aorta , this may involve the left subclavian artery, which may bulge laterally and make the radiographic appearance more confusing The aorta on both sides of the stenosis may be dilated , proximally the dilatation, sometimes aneurysmal, may be partly due to the associated hypertension, but below the stenosis this cannot be so, and no entirely satisfactory explanation has been found It is known, however, that the vessel walls near the coarctation may be defective and lacking in elastic tissue, and this may be connected with a lack of the stimulus normally provided by arterial pulsation The presence of a high resistance in so large an artery produces considerable changes in the circulation In patients who survive, the adjustment is remarkably successful, and the blood-flow in the lower limbs is usually quite normal The collateral circulation which develops takes much of the total flow , but although this is normally very free it has a higher resistance than the normal channels, and the drop in pressure across these resistances is offset by a rise in the proximal blood-pressure This in turn calls for a compensatory mechanism to moderate the flow through the upper half of the body, and in fact the forearm flows are normal The hypertension, however, usually contributes to the patient's death, which may be due to cardiac failure, subarachnoid hæmorrhage, or rupture of the heart or aorta but a few succumb to bacterial endarteritis, usually affecting the aorta just below the coarctation

The diagnosis of coarctation, provided the condition is kept in mind, is usually simple The finding of a high blood-pressure, especially in a patient of good—or even superior—physique should lead to palpation of the femoral pulses, which are always diminished and often absent The femoral pulse, when present, is delayed, compared with the radial pulse, mainly owing to the slow rise in the pulse wave , the very slight lag occasioned by the longer collateral route is imperceptible[2] This diminution of the pulse wave, however, does not mean that the blood-pressure in the legs is very low

Direct measurement from the femoral artery shows that, though the pulse pressure is small, the mean pressure is lowered by no more than 10–15 mm Hg and always by much less than the reduction in systolic pressure, which may be 80–100 mm Hg This is because the pulse wave is heavily damped by the resistance of the collateral vessels and the distensibility of the distal aorta. The position is analogous to that in patients with a collateral circulation around a thrombosis of a large artery , EDHOLM et al[6] have found that in the affected limb the flows and pressures are relatively normal

The drop in pulse-pressure may silence the Korotkoff sounds, thus making it impossible to take the blood-pressure by the auscultatory method and reinforcing the mistaken impression that the leg pressures are very low Many other clinical signs of coarctation have been described, but though they may occasionally draw attention to the condition they add little or nothing to the certainty of the diagnosis Perhaps the most valuable of these additional signs is the presence of dilated collateral vessels over the back , but these are not always visible and are seldom definite in patients under the age of 10 years Occasionally murmurs are audible , but they are not usually a prominent feature and are certainly of no importance

Radiology plays little part in the d coarctation, since this can be so readily es clinical examination, but occasionally notching ribs may draw attention to the disorder The which are on the inferior margins of the ribs to the elongated and tortuous intercostal they participate in the collateral circulation ing blood from the shoulder-girdle and chest into the aorta (The first one or two ribs affected since their intercostal arteries arise subclavian artery—i e , above the coarctation many years this appearance has been pathognomonic of coarctation It is not ever, in every case, and is seldom distinct in under 10–12 years of age In a few cases no been seen in congenital cyanotic heart-disease, may also develop after a successful attempt to the pulmonary circulation by establishing adhesions[8] It is usually best seen in the and is clearest about 2–3 inches lateral to the It should not be sought along the necks of the these areas so often appear wavy The heart may be rounded or globular but is not usually enlarged, and if left ventricular enlargement nounced aortic reflux should be suspected The knuckle may be absent , but just as often there many “ aortic knuckles,” from shadows thrown kinked subclavian artery and by the dilatation aorta above and below the constriction The the coarctation is not easily displayed by plain graphy , but it may sometimes be demonstr lateral or oblique tomograms, or by careful tion with a barium swallow[9] Not infrequently appearances are complicated by the presence aneurysm above or below the constriction, or from the narrowed segment itself or from an costal artery Angiocardiography should alwa done before the patient is operated on, since this show the length and calibre of the narrowed se and the disposition of the great vessels Great ca is needed in interpreting the filling—or non fill aneurysms, for the degree of filling is not alw reliable indication of the flow[10] Adequate p may occasionally be obtained by intravenous inj but direct aortography[11] gives shadows of greater density and contrast, and this method always be used

Coarctation was first corrected surgically CRAFOORD[12] in 1944, when he resected the nar segment and did an end-to end anastomosis in year-old boy Simple resection is still the oper of choice , but in certain circumstances, as Gr has pointed out, end-to-end anastomosis m impossible, and then grafting with a length of aorta may be the only way of bridging the gap will think, with BROCK, that no-one should sta operation for coarctation unless he has a graft bag—it will not always be used The graft need be viable, as judged by tissue culture , it seems as a scaffold into which new intimal and itial coats can grow The best age for operation ot yet been decided On the one hand it seems grafts do not grow with the rest of the body, and d therefore not be inserted until the patient is full grown and has a fully developed collateral lation, while, on the other hand, degenerative ges may develop in the aorta and elsewhere during scence and thus increase the technical difficulties operation Furthermore any unnecessary delay desirable since coarctation is a constant threat to Up till now the supply of grafts has been very ed and the surgeon has often had to wait until s available, but the results of recent experiments erilisation and preservation of grafts have been encouraging,[4 14] and it may be possible soon to lish a graft bank. It is not yet known whether theoretical risks as shrinkage of the graft or, con ly of aneurysm formation will be encountered in ice but this uncertainty should not hinder work h has already provided brilliant short-term results *y may be fatal, and many surgeons can recall* nts who have died while their names were on the ing list

Vagaries of Intelligence

is widely believed that every child is served out *a limited* quantity of intelligence which—like the of him—can go on developing till it reaches the of its capacity, but which cannot otherwise be nded The mature intelligence is thus thought to a direct, possibly predictable, relation to the al ration issued by heredity, just as the size of a nese pith flower which has expanded in water nds on the original size of the bit of pith This tical and convenient assumption is backed by the lligence quotient (I.Q.), which is taken to remain hly stable throughout life Many have criticised reliability of tests for assessing the I.Q., and almost many have thrown doubts on the underlying mption but these have had less publicity On ther page, Mr A D B Clarke PH.D and Mrs M Clarke PH.D bring fresh evidence that the mption is untenable and a group of papers *ntly published strongly support their contention* t intelligence far from being a fixed quantity, may y considerably during a lifetime

r J Tizard, PH.D,[15] discussing criteria of mental normality, deals first with weaknesses in our hods of testing A child's performance in tests is no means constant from one test to another so n a group of children are tested and retested by a ndard method, such as the Binet test, though the *rage* I.Q. remains much the same, *individual* I.Q.s y vary considerably

hus in a test with a test retest correlation of 0·9 on nediate retesting and a standard deviation of 10 nts, one child out of every three who gained average res of 100 on the first test would on being retested, re above 107 or below 93 because of errors of asurement ; and one out of every ten children with rage scores of 100 would score above 112 or below 88 the second test.

An I.Q. of less than 70 is very widely accepted as dence of mental subnormality—sometimes on the lts of a single test It seems that one child in three who scored 80 at a first test might, at a second test, fall into the subnormal group Again, early revisions of the Binet test were believed to have a standard deviation of 12–13 points, and an I.Q. of 70 points thus fell about $2^1/_2$ *standard deviations below the* mean, and cut off 1% of the population On some recently devised tests however, the standard deviation is nearly twice as much, and an I.Q. of 70 falls just over one standard deviation below the mean and so cuts off 10% of the population Another difficulty is that the standard deviation sometimes varies for children of different ages

> Thus the 1937 revision of the Stanford Binet test has standard deviations varying from 13 points at the age of six to 20 points at the age of twelve and an I.Q. of 74 achieved by a six year-old on this test is thus equivalent *to an I.Q. of 60 achieved by a twelve-year-old.*

Tizard also points out that even if scales for measuring intelligence were absolutely reliable—in the sense that qualified observers would agree perfectly about each person's standing on the scale—it would still be impossible to predict infallibly the subsequent performance of those tested, for our present tests give only one point on a curve of growth and development and "the slope of the curve is not the same for all individuals" Many studies have been published about this fluctuation in performance He quotes the findings of *Honzik Macfarlane, and Allen*[16] that tests of two year olds predict performance at the age of five to an extent little better than chance and though prediction improves as the age of the child rises it is always hazardous

> In a given group of children the I.Q. changed, during the growing period of six to eighteen years by as much as 30 or more points for 9% of the group by 20 or more points for 33% and for 15 or more points for 60%; it changed less than 10 points for only 15% Thus for one out of every three children a prediction made at a six year-old test would be wrong by 20 points at the age of eighteen

As Clarke and Clarke say "it is clear that in the general population the concept of a rigidly constant I.Q. is contradicted by the facts, I.Q. constancy over long periods of time during the years of mental growth is the exception rather than the rule" Some findings *reported by Dr Nancy Bayley,[17] from the Institute* of Child Welfare at the University of California, bear on this

> A study was made of a group of adults of superior intelligence who were tested by a concept mastery test designed by members of the Terman gifted study group at Stanford and tested again twelve years later Changes in scores between the two testings were compared on the basis of scores in the final test sex age-group educational level occupational status and estimates of general success ; and some individuals in each of these classifications had improved their score over the first testing among them the two oldest people in the group—who, moreover scored higher in both tests than the group averages.

Whatever may finally prove to be the predictive accuracy of intelligence tests for adults those available for testing young infants even when they are carried out by an experienced and informed tester, certainly have none Prof Jean Walker Macfarlane, PH.D,[18] who has studied the value of such tests for predicting the performance of children who are to be

[18] *Bull. World Hlth Org* 1953 9 409

adopted, also finds that the predictive value increases with the age of the child, thus for children aged nine years or over performance at eighteen can be predicted fairly accurately for six or seven out of ten—though this is too late for most would-be adopters But the fact is that the tests are influenced by many things besides the child's intelligence and its developmental curve—by his growth-rate, moods, physical well-being, freedom from anxiety, liking for the examiner, and willingness to cooperate in the test "Test performance," as MACFARLANE says, "measures the level of functioning, which indeed has as one of its elements intellectual capacity or potential" Perhaps the growing use of such tests is encouraging us to place too high a value on intelligence Many other factors go to make a useful man, as TIZARD puts it "Intellectual and temperamental qualities, for example, are not closely associated with each other, nor is school success necessarily a good predictor of occupational adjustment" Thus the performance of a brilliant man may be hindered or completely overthrown by his temperamental or emotional defects, while a duller man who is easy in himself and with others may far outstrip his achievement

We have no clear idea of the effects of education on intelligence, but it evidently has far more influence than the concept of the stable intelligence quotient suggests TIZARD quotes R S WOODWORTH as saying "radical differences in education can create substantial differences in intelligence, as far as intelligence is measured by our tests" Studies of normal children have shown, in some, consistent upward or downward trends in I Q over periods of years, some of the changes amounting to as much as 50 points, while mental defectives taken from a bad environment, and placed in a better, show a gain in intelligence, as measured by the I Q CLARKE and CLARKE, in their experiment with 59 mentally subnormal patients, illustrate this fact again, and in a further 11 cases they were able to show that a history of a bad or a good home probably has a predictive value for the child's future progress They ask whether such relatively spontaneous changes can perhaps be accelerated and improved Their findings are, at all events, a good argument against a too rigid segregation of patients according to mental level the introduction of a few brighter children into a ward of low-grade imbeciles can produce remarkable advances in some who have seemed incapable of improvement Incidentally, the proportion of feeble-minded children who grow up into essentially normal adults is always high—about half to three-quarters in most studies A study made over fifteen years of 206 adults who as children had been classified as mentally subnormal showed that over 80% were self-supporting, 80% were married, and 80% of these had children The number of children per family was slightly less than the national average, and their mean I Q was 95

Genetics has as yet no clear message for us on this difficult problem Prof L S PENROSE[19] points out that eye, hair, and skin colours, stature, length of life, personality, and mental ability are each dependent on more than one gene, and the same applies to abnormal behaviour traits such as the common psychoses, epilepsy, psychoneuroses, and mental deficiency Moreover, the definitions of such characters as insanity, criminality, and mental defect are largely social standards which vary enormously in cultures "It is very difficult," he says, "to the genetical from the environmental variation in these traits" Adoption pr experimental situation in which the effects of environment can be critically studied C are not safe in making predictions about the gence of children from the study of one or parents

SKODAK and SKEELS, quoted by MACFARLA 63 children raised in foster homes, and also the mothers Only 20% of the mothers, as against the children, had I Q s over 100, and of 12 moth I Q s below 70, one had a child with an I Q abov and all but one of the rest of the children had 70 In another study of 269 family groups co nearly 1000 people JONES and CONRAD found is a statistically significant relation between the gence of parents and children, so that a prediction made with confidence for two or three out of children This is certainly better than chance, not of much practical use, since it is presumably sible to know in advance to which two or three out ten it applies

Taking it all round it looks as though f differential birth-rate is causing a decline national intelligence are premature, being co too simple a spirit There is a great deal of done on the normal fluctuations of int different ages, under stress, and in different and emotional environments before this question can be debated in an informed way even turn out that intelligence is less like a water-flower than a balloon, which expands as stretched

Annotations

AFTER OPERATION

IN his Harveian oration to the Royal Colle Physicians last week Dr George Graham departed precedent by showing charts, and though his of the Value of Physiology in Medicine began wi past it ended well ahead of the ordinary hospital p of today

His main theme was the application of physi knowledge to the care of patients after operation particularly the need to meet deficiencies of pota The first step in the treatment of postoperative was taken, he said, when Sydney Ringer in discovered that the frog's heart could be kept ing with isotonic saline solution made up with water but not with distilled water ("Physicians expressed contempt for results that come from pithed frog, yet the frog has been of great value medicine") It is now known that the more seve operation, the more potassium leaves the muscles, and loss of potassium from tissues and blood may produce syndrome which Whipple in 1923 called pancreatic mia Symptoms and signs of potassium deficiency inc muscular weakness, abdominal distension, ileal cramps, nausea, vomiting, lethargy, apathy, and de sion, with characteristic electrocardiographic ch These effects can and should be prevented, in debili potassium deficient patients who are to undergo operations, by preoperative treatment But injudi postoperative administration of potassium can cause poisoning, and skilful steering is needed to the Charybdis of deficiency without running on to Scylla of excess Skill is required because the caused by excess, though not so clear-cut as those iency are by no means dissimilar thus weakness ie limbs betokens too little potassium while true ysis betokens too much—a situation resembling in diabetes where the patient in coma may be ring from either too little or too much insulin. The of poisoning is reduced by always administering se at the same time, and potassium should never iven in the first 24–30 hours after operation (when blood potassium level may be high) or at night s some senior person is at hand to interpret any ge in the patient's condition In fact Dr Graham ves that the proper application of physiological vledge to maintaining the electrolyte balance of any ut who has undergone a severe operation needs the efforts of the surgeon and a physician, both with iological instincts and a knowledge of cardiology and biochemist—besides the registrar the house surgeon well trained nurses On the principle if prevent why not prevented ? ' this challenge from a senior ician speaking from the seat of Harvey is one that ot be ignored

TUBELESS GASTRIC ANALYSIS

On many patients a fractional test meal[1] is rather rdeal even when expertly carried out and any ble method of gastric analysis that does not call he passage of a gastric tube must command attention l and his fellow workers[2][3] in 1950 devised an int tubeless technique for detecting achlorhydria depends on the power of the hydrogen cation) of the free hydrochloric acid of the gastric juice pH of 3 or less to displace the quininium cation +) from a quininium resin compound When compound is ingested the quinine hydrochloride ied is rapidly absorbed from the small intestine and dine is excreted in the urine within 15 minutes The ine can be rapidly and simply estimated by a simple hod based on its fluorescence in ultraviolet light

his method has been reported on favourably in U.S.A[4][5] and has been carefully studied in this ntry by Harkness and Durant[6] In 200 subjects the hod was compared with an alcohol or alcohol plus amine test meal Comparison was impossible in nstances—in 13 the alcohol test meal was unsatis ory and in 7 the quininium resin method failed failures of the alcohol test meal were the more erous, and the more difficult to correct since the fault in the patient's condition (gastric hæmorrhage sistent vomiting refusal to swallow the tube &c) tubeless analysis by contrast had 4 failures arising n nursing errors administration of the resin and ection of urine; and these tests were later repeated essfully In 3 patients, however difficulties in the trol of micturition made the test impossible An ellent measure of agreement was found between the methods in the assessment of achlorhydria It found that excretion of 27 mg or more of quinine icated the presence of free acid Even with achlor dria, some quininium is released from the resin ause other ions besides the hydrogen ion displace the inium These other ions include sodium and assium *which are normally present in the secretions* l, more important, aluminium calcium barium l, and kaolin—substances which are commonly uded in medicines for patients with gastric dis er or anæmia Anomalous results were obtained ess such medication was stopped at least two s before the test Twice a positive reading was ained in a patient with a partial gastrectomy in whom two alcohol plus histamine tests showed achlorhydria but this is really understandable because of the variable factor of regurgitation through the stoma of neutralising juices from the duodenum and jejunum Malach and Banks[4] found a good correlation in 9 patients who were studied after gastric resection A false negative result may be found when defective renal function impedes excretion of quinine and this invalidated the test in 3 cases of the series reported by Harkness and Durant In patients with peptic ulcer one would not expect complete agreement between the alcohol and quininium resin technique Watkinson and James[7] noted from 24 hour gastric analyses that free hydrochloric acid was detected in no less than 10 out of 12 patients who had achlorhydria according to the usual histamine tests In contrast however complete anacidity was found throughout the day in patients with addisonian anæmia.

A serious disadvantage of the tubeless gastric analysis is that it does not indicate the level of acid secretion—Harkness and Durant found no correlation between the levels of excretion and the amount of acid judged by the test-meal But this disadvantage might be overcome through studies on the rate of acid secretion As Avery Jones[8] has observed, this new test may be useful in the investigation of patients with suspected addisonian anæmia but it is unlikely to have any other serious indications. Even test meals have only a limited value in the investigation of dyspepsias, but in the diagnosis of carcinoma of the stomach the appearance of the gastric juice may provide a useful clue

'WITH A BLUSH RETIRE'

In one of his tales of the future Kipling made a woman remark, in the pride of her youth 'I'm only forty' By this stroke he indicated a complete reorientation to the question of age people in that coming time expected to live to round about a hundred We—their ancestors, in a manner of speaking—are perhaps making the first move towards their adjustment we are trying to accustom ourselves to an expectation of life, at birth of 66 for men and 71 for women and since this average is affected by the mortality at younger ages and especially the infant and neonatal mortality many of us are going to live a good deal longer than that Moreover since the forces tending to keep us alive are to a large extent the same as *those operating to keep us well, many of us will* feel fitter than did aged people in the past There is no escaping the truth however unpalatable that more can be expected of us than of our forefathers. In their first report, the National Advisory Committee on the Employment of Older Men and Women[9] make this point afresh recalling the good reasons we now have for believing that many men could go on working after 65 and most women after 60 and emphasising three excellent reasons why they should Greater length of life of course is one reason and the rising proportion of older people in the community is another; the third is the country's need of workers.

The committee found themselves handicapped however by lack of information in making estimates of the numbers who might postpone retirement given the opportunity for further work At present some 400 000 men aged 60–69 and some 2[illegible]0 000 over 70 are going on working These represent just under half the total number in the 60–69 age group and about a quarter of those over 70 Over 100 000 in the unoccupied group aged 60–69 are chronically sick and unable to work but that leaves a further 350 000 who might possibly return to work given encouragement We need to know what kinds of encouragement and the Ministry of Pensions and National Service are now inquiring into the reasons

why people of pensionable age retire or stay at work It is possible, of course, to guess at some of them lack of the chance to continue, and a feeling of having done enough already, are two likely deterrents Many women do two jobs for part of their working lives—a paid job of some kind and the job of housekeeping for their families They probably accept with relief the chance to take a pension and do only one There are other difficulties about increments to pensions, which we reviewed fully last year[10]

A fixed retiring age is not common among manual workers, but is often applied to clerical and administrative workers, and has led to a widespread feeling that retirement at such an age is a right There is no medical reason to support the fixed retiring age, on the contrary Firms hesitate to change or vary the age, however, because of difficulties about promotion of junior staff The committee insist that it is time to review all these difficulties and get rid of some of them The criterion for employment should be ability, not age

They have studied more fully than has been done before the obstacles facing the older professional people who want to go on working These may be encountered long before retiring age a typical case is that of the officer leaving the Forces in his forties, who may apply in vain for post after post Employers are chary of appointing him, sometimes because there are actuarial difficulties about latecomers to pension schemes, sometimes because they are diffident about asking an older man to take lower pay than his qualifications seem to demand, or conversely fear that he may not be worth the pay appropriate to his age There are also traditional reasons—a custom of recruiting only school or college leavers, an ill-founded belief that older dogs cannot learn new tricks There is evidence that the middle aged and elderly are more adaptable and trainable than is commonly thought, and that they are more reliable and less accident-prone than the young The numbers in the professions who are adversely affected in this way are not perhaps great, but they represent a waste of ability and expensive training In general the committee urge that firms should modify their rules so as to be able to admit the occasional late entrant and to keep on the efficient older worker after he has reached what they earnestly request should now be called the *minimum* age of retirement

POLIOMYELITIS VACCINATION TRIALS

Six months ago we discussed[11] some preliminary trials of poliomyelitis vaccines At that time Salk[12] had reported the results of vaccinating 161 persons with inactivated vaccines prepared from tissue-culture virus These preliminary results were encouraging, there were no ill effects from the vaccination, and many of the volunteers developed antibody to all three types of poliomyelitis virus Recently, Salk[13] stated at a meeting of the American Academy of Pædiatrics that 637 children and adults have now been vaccinated with several experimental vaccines, and again the vaccines appear to be safe and capable of stimulating the production of antibodies After Salk's statement a spokesman of the National Foundation for Infantile Paralysis reported that ambitious plans were under way for testing the protective powers of poliomyelitis vaccines Trials are being planned for early in 1954 and it is expected that several hundred thousand children will be vaccinated

While it is encouraging to see rapid progress in this important work, many people will be disturbed at the huge scale of the projected trial It is possible that the risks of a trial of this kind are very small, but there has been little time or opportunity to find them out The production of a few hundred thousand doses of vaccine the growth of all three types of poliomyelitis tissue-cultures of monkey's kidney, and the virus then be inactivated by formaldehyde in such that they lose all infectivity but retain their potency, and the time available for these preparations seems short Moreover, a trial scale will be much publicised and the public will the vaccines to protect against paralytic polio and produce no ill effects If they do not justify these expectations, there is a risk that the view of poliomyelitis vaccination may be prej some time to come

SEX CHROMATIN AND HERMAPHRODI

The disorder in normal sex differentiation human embryo which leads to hermaphr unknown Both sex chromosomes and autosomes genes which influence gonadal differentiation, is uncertain whether the development of the sex organs in man is determined thereafter by the hormones of the fœtus, by its genic constitution, a combination of the two

In the absence of knowledge of its causat aphroditism has been classified on an anato taking into account the histological appearances gonads and the morphological anomalies of the and external sex organs The true hermaphrod whom both ovarian and testicular tissue are rare, but pseudohermaphroditism (classified as or "female" according to whether the gonads or ovaries) is not so uncommon, and its prevalence population has been estimated to be as high as 1000[1] The rearing of these infants, however, —and understandably—at variance with their sex Many of the more severe cases of female anomaly—which are usually associated with overactivity—are raised as boys, and intersex with purely feminine external genitalia are raised as girls Where the external anatomy is vocal sexuality, considerable difficulty in attribut may arise, and Williams[2] suggests that equivocal are best treated as boys

The shortcomings of present methods of class hermaphrodites have led Moore and his colleag to develop a method of determining sex which pendent of the morphology of the sex organs use of Painter's observation[6] that sex chrom show histologically a characteristic deep staining perty, they investigated the stained appearances nuclei in the cat Nerve cell nuclei were first observation because of their large size and clear and it was found that in stained material from the cat a distinctive chromatin mass near the nucleol visible with an oil immersion objective in a high tion of cells, but was rarely seen in the nuclei of male cats This sex difference was in the cell nuclei of the other tissues and of the cat, and also in a number of other m species, including man Moore et al suggest that "sex chromatin" is derived from the sex and that the fusion of the two heterochr X chromosomes in female cells gives rise to a deeply staining chromatin which is readily visible lack of distinguishable sex chromatin in the attributed to the small size of the Y chromosome XY combination resulting in a chromatin mass too to be recognisable as an intranuclear entity App observation to man these workers were able by ying stained sections of skin biopsy specimens to r correctly the sex of 70 normal people They tenta ly suggest that skin biopsies from intersex individuals indicate the dominant sex, and cite two such s in which the chromosomal sex tallied with the ure of the gonads Moore et al suggest that investiga of the nuclear sex chromatin in a series of known s of hermaphroditism may establish a relationship ween the type of intersex anomaly and the chromo al sex of the subject, and perhaps throw light on the logy of the condition At any rate as a diagnostic sure this ingenious method may prove of considerable ic especially in infants

ANOTHER NEW ANTIBIOTIC

VERY *wide range of organisms are attacked* by the biotics now in common use; and additions to the are valuable usually as a second line of attack when nisms have become resistant to the usual antibiotics latest addition is carbomycin

arbomycin is produced by a soil actinomycete *ptomyces halstedii*[1] It is a crystalline monobasic stance containing carbon hydrogen and nitrogen a molecular weight of about 860 It is sparingly ble in water although salts such as the hydrochloride sulphate are water-soluble The antibacterial ctrum of carbomycin closely resembles that of hromycin although against the majority of sensitive ins erythromycin is the more active weight for ght Both agents are active against gram positive ci and neisseria and to a lesser extent against strains æmophilus, but they are essentially inactive against coliform group[2,3] The pneumococcus and hæmolytic ptococcus are among the most sensitive bacteria in o while staphylococci (including those resistant to er antibiotics) and enterococci are slightly less so The vity of carbomycin against staphylococci resistant to er antibiotics indicates a possible use for the drug unfortunately these organisms readily become resistant arbomycin in vitro Furthermore, the development carbomycin resistance is accompanied by erythro cin resistance[3,4] There seems to be no cross stance however between carbomycin and penicillin, ptomycin chloramphenicol aureomycin, or oxy acycline (terramycin)[4]

eports of clinical trials of carbomycin are at present but preliminary results are not encouraging hough the pneumococcus is highly sensitive to this ibiotic in vitro the treatment of pneumococcal umonia with it gives very uncertain results. 31 cases e treated by Finland et al.,[5] who concluded that the ults were ' distinctly inferior to those observed with of the antimicrobial agents currently recommended use in these infections. Pneumococci disappeared idly from the sputum of only 3 patients they were l present in the sputum of the remainder for up to days from the start of carbomycin therapy Of 7 ients from whose blood pneumococci were isolated ore therapy 5 continued to yield positive cultures for to six days Clinically a good effect was con ared to have been obtained in only 6 patients Bunn l Cook[6] treated with carbomycin 8 patients with umococcal pneumonia. Of these 8 4 responded isfactorily and in another the condition cleared after weeks; while the remaining 3 were classed as clear treatment failures, bacteriologically and clinically ' Blood-cultures were still positive forty-eight hours after the start of therapy in 2 of these patients

If infections caused by highly sensitive organisms respond poorly to carbomycin, the hope of benefit in those caused by less sensitive bacteria such as *Staphylococcus aureus* is very small. Hewitt and Wood[4] treated 9 patients with *Staph aureus* infections (3 pneumonia, 2 bacterial endocarditis, 1 carbuncle 1 skin sepsis 2 urinary tract infections) The blood-culture of one patient with endocarditis became negative but after five days the patient died from cerebral embolism Carbomycin therapy also caused complete resolution of the abscesses of the patient with skin sepsis. No effect, however, was observed in any of the other 7 patients Similarly Finland et al[5] observed no change in a patient with staphylococcal empyema treated with carbomycin *or in a patient with staphylococcal pyelonephritis and* bacteriæmia Brief reports of the value of carbomycin in other bacterial infections are no more encouraging

It seems, then that carbomycin is unlikely to take an important place in the treatment of bacterial infections Clearly it should never be the first choice for serious infections since it might deprive the patient of an antibiotic known to be effective As a second choice, however for patients who fail to respond to the usual antibiotics, carbomycin may occasionally be of value

CEREBRAL ANGIOMA

INCREASING use of carotid angiography has focused attention on arteriovenous angiomas of the brain and the observations by Olivecrona and Riives[7] in Sweden, on the possibilities of operative removal of these lesions has made their recognition of more than academic importance *The common symptoms are epilepsy,* subarachnoid and intracerebral hæmorrhage focal cerebral signs, and headache Mackenzie[8] has studied in detail the early manifestations in fifty cases. Similar lesions are found around the mid brain[9] but he has confined his attention to supratentorial angiomas

Arteriovenous angiomas are congenital lesions; but, as Olivecrona has shown by angiograms repeated at an interval of ten years they may increase in size, while symptoms may also be exacerbated by complications such as hæmorrhage and possibly thrombosis. In Mackenzie's series the first symptom arose before the age of 30 in 70% of cases and during the first decade in 10% Although headache was a common early symptom it was usually epilepsy or an intracranial hæmorrhage that drew attention to the presence of a serious lesion Epilepsy was the presenting symptom in 16 patients, and *in all except 1 of these there were focal features in* some or all of the attacks these features were usually recognised by the patient in the early stages of the fit but in a few instances a witness's account was needed. In some of these patients there was transient hemiparesis or dysphasia after the fits and by the time they came under observation at hospital 11 had permanent focal signs In 15 patients the first indication of the lesion was an intracranial hæmorrhage usually this was both subarachnoid and intracerebral but in 3 cases it was apparently into the brain substance alone without leakage into the subarachnoid space With the almost routine use of carotid angiography in patients who have had a subarachnoid hæmorrhage arteriovenous angiomas have been identified as the source of bleeding in about 10% of cases.[10] The clinical sequence of subarachnoid hæmorrhage followed by epilepsy may occasionally arise from intracranial aneurysms but should suggest the possibility of an angioma the opposite sequence of epileptic attacks followed by a subarachnoid hæmorrhage is however extremely rare with aneurysms and is

highly suggestive of an angioma Severe headache without special characteristics was a common symptom in the Swedish cases , and Mackenzie noted it as the presenting feature in 12 of his 50 patients He found that in some patients it had some migrainous features , but in retrospect it could usually be differentiated from constitutional migraine since the unilateral headache tended always to be felt on the same side of the head (the side of the angioma), while commonly in migraine opposite sides of the head are involved in different attacks The most characteristic sign of a cerebral arteriovenous angioma is an intracranial bruit A bruit is occasionally heard over a highly vascular cerebral neoplasm or in patients with Paget's disease of the skull, but usually it indicates a vascular malformation The bruit may be faint and intermittent and at times is better heard over the eyeballs than over the skull Olivecrona recorded a bruit in only 25% of his first series of cases,[11] and did not regard it as a very important diagnostic sign In Mackenzie's patients a bruit was heard in 24 of the 48 patients in whom it was sought It was relatively less common in patients in whom an intracranial hæmorrhage had occurred, the probable reason being that the more *deeply situated angiomas tend to bleed* *In a suspicious* case careful and repeated auscultation of the skull and eyeballs is certainly worth while, but the absence of a bruit in no way excludes the diagnosis of angioma

Other physical signs are variable , sometimes motor and sensory hemiparesis or hemianopia are found, and such signs are especially common after an intracerebral hæmorrhage Olivecrona suggested that in the presence of these signs without a history of massive hæmorrhage the cause might be thrombosis or anoxæmia of cerebral tissue due to most of the relevant blood-supply being shunted through the angioma , while Mackenzie believes that small hæmorrhages may take place and destroy cerebral tissue The diagnosis is finally made by carotid angiography ; and surgical treatment must always be preceded by this investigation, which reveals the source of the angioma's blood-supply

MOTHERCRAFT TRAINING IN PRISONS

TRAINING in parentcraft begins at birth, for the adult's ideas on the way parents behave are inevitably grounded on the way his parents behaved to him Not a few of the mothers sentenced for neglecting their children, and sent to the new hostel at Birmingham Prison for a training course in mothercraft, argue that they were convicted for something no worse than their parents did to them—without being sent to prison for it This hostel has been in action now since February, 1952, and in their latest report[12] the Prison Commissioners are able to give a cautious account of the way it is working Situated inside the prison grounds, in a building which used to be officers' quarters, it can receive 12 women at a time These are sent from prisons all over the country, the only qualifications being that they should be of star class, able to fit well into hostel life, and with long-enough sentences for them to complete the course Sometimes not enough women convicted of neglecting their children have been available, and then vacancies in a course have been filled by other star women prisoners who can profit from it

The courses have been arranged by the Birmingham education authority, public health authority, and children's committee, and have to be very simply planned , for as the commissioners say, "although the home conditions that led to the charge were usually appalling, this was often the result not of poverty but of wasteful and unintelligent spending, bad housing, which readily induces slovenly habits, unhappy marital relationships, or the low mentality and poor physique of the They return, on discharge, to the conditions in have already failed , so the aim of their insu to teach them to use whatever cooking equipment have in their homes, and the elements of house- sewing, washing, and ironing Some cannot rea write, and so have to be encouraged to memorise instructions They are not particularly anxious they arrive, to learn anything The chaplain of prison, who gives a little account of these women, that the teachers are confronted with an "a degree " of ignorance and idleness but that the not unduly discouraged by this Most of these grew up in surroundings where overcrowding, and broken marriages were commonplaces standards have thus always been low , and as own children came they have accepted a pro decline, even in their own low standards In one all bedding and all furniture had been sold—or to the hire-purchase firm—until nothing and the family lived in the house on the floor with n in the way of furniture But the women r training, especially when they have once had the surprise of finding *that they too can do things* Nothing is a better tonic for the demoralised little success It is interesting that few of the reveal any real degree of poverty most of the could have maintained their families on a modest reasonable standard, and where there were many the family allowances, properly spent, would sufficed to feed them The difficulty lies in the of the parents to put first things first—sometimes in an unparental inability to put the children themselves The chaplain cites the cases of a without bedding or warm clothing and with arrears, where there was nevertheless a good set , another where the children were underfed the father and mother afforded a night out every day and a third where the mother's first charge on housekeeping money was 3*s* 7*d* a day for for herself Sometimes the father gave his wife small a proportion of his earnings for *housek* and in two cases he had been long out of work , the main the trouble was a complete inability to wisely The instructors have therefore taken pains to teach the women how to budget for spending Squalid housing presents a more diff problem, but the mothers are brought to rea that rooms, however bad and crowded, can be kept and probably warm Overcrowding is the worst of decent standards when the children have to on the floor because there is no room for a bed, dirt dirty habits are almost inevitable Drinking gambling seem to be far less potent causes of child ne than overcrowding they are pursued, but not recklessly among the English today

The real test of the mothers attending these co comes, of course, on their discharge. The Wom Voluntary Service are doing good work by a "friends" for those who want them, to stand by when they return home Even when they have for such a friend some of the women do not keep touch with her , and though it is too early to asses effects of the course, the W V S reports suggest some soon slip back into their old ways No d this is because their circumstances are still too for them , and the prison mothercraft course, it has given them a better idea of what to work for, naturally not been able to reconstruct their in a matter of a few weeks What they probably is the help of a family service unit for a few m whose members could work with them in their own h and teach them to build on the foundations which mothercraft course has so well and truly laid

BASIC GROUP PRACTICE

HOW IT CAN BE DONE*

JOSEPH S COLLINGS
M.B B Sc (Agr) Sydney

N two previous articles I suggested that basic group ctice might solve many of the problems of general ctice today and thus stabilise the National Health vice In the second article I set out some of the tical details on which the success or failure of this e of practice depend In this third article I propose discuss what it costs to start and run a basic group ctice and how this kind of practice can be developed hin the framework of the N H S

Finance

ly estimates of the capital costs and running expenses on a general knowledge of what this type of practice ts in places outside Great Britain adjusted to the ue of money in Britain today They are overestimates ier than underestimates I have based my calcu ons on the five-doctor group which is probably the t size Five doctor groups are of course not practicable rywhere in Britain but my figures can be scaled down groups of four three, and two doctors and for those king alone in rural isolation

hus I suggested that a five-doctor group should ploy 2 nurses 2 secretaries (1 acting as receptionist) 1 relief nurse-secretary For smaller groups the ie staff would be

Four-doctor groups	2 nurses and 2 secretaries
Three-doctor groups	2 nurses and 1 secretary
Two-doctor groups	1 nurse and 1 secretary

he equivalent of these in people who can interchange s or part time people who can work to a roster

he cost of converting dwelling or business premises a medical centre will vary with the local value of perty More often than not premises will be rented leased rather than bought outright Once a suitable lding has been found it can be radically adapted and medical centre equipped satisfactorily—bearing in d that much of the equipment will be contributed n the surgeries of the doctors of the group—at an ial cost of approximately £1000 per doctor or £5000 a five-doctor group If the centre is to be built from ground up, it will cost about £3000 per doctor or 000 for a five-doctor group

ho heaviest running expenses are staff salaries and t (*assuming that the property is not freehold*) The ual cost of salaries for a five-doctor group would be roximately :

2 nurses	£1000
1 secretary	£400
1 receptionist	£400
1 relief nurse-secretary	£300
	£2100

ent will vary but should not exceed £750 per annum any reasonable lease The other main expenses are

Car maintenance	£1000
Telephone	£150
Stationery	£200
Journals, study allowance society memberships &c.	£500
Gas and electricity	£200
Insurance	£150
Depreciation at 5% (considered as a £5000 investment)	£250
Contingency fund	£100
	£2550
Staff salaries	£2100
Rent	£750
Total	£5400

onsidering this against the gross income from a panel 2 500 (estimated at £1 per head) the running expenses about 42% of gross takings This makes no allowance for income from sources other than capitation fees or for mileage allowances for running cars The running expenses of comparable groups which I have studied in other places were within the range of 30–50% of gross takings

On this basis the net income to be distributed among *the doctors working in the group is £8000 or £1600* per doctor This figure should be a minimum net average and can of course be considerably higher

Framework Offered by N.H S

In its first five years the National Health Service has done little to stimulate the development of group practice Hopes were centred at first on the possibilities of ill defined and little understood health centres ; but these hopes have only been fulfilled in two or three places, and by now have lost their charm both for the general practitioner and for the Exchequer They are monuments to the local authorities and the outcome of a do nothing ' policy in regard to the main structure of general practice

The capitation system of payment and the tax concessions offered to the individual general practitioner are both strong deterrents to the development of group practice The capitation system subsidises quantity and penalises quality Attempts have been made to *adjust* the original capitation fee so as to equalise the remuneration of the small list and big list doctor But the basic evil of the capitation system remains According to elementary economics payment by salary would be more equitable but most doctors resist strongly any suggestion of remuneration by salary and this resistance has doubtless been strengthened by the generous provisions of the Danckwerts award

The general practitioner is given generous tax concessions. Allowances for practice expenses for his private home when the surgery is in the house and for his car, &c all make it advantageous for him to continue to practise alone as he does today on minimum actual expenses but maximum theoretical expenses

Whether we believe that the doctor receives too little or too much of direct remuneration or that his tax concessions are overgenerous or niggardly we must if we are honest admit that it is to his financial advantage to resist any change in the present administrative structure which might (*a*) reduce the maximum size of his list or (*b*) make possible a closer scrutiny of the expenses on which he claims tax concessions The present structure thus deters rather than encourages improvements in the organisation of general practice but since it is unlikely to be altered radically we must try to devise, within this framework means of stimulating instead of deterring better methods of practice

Inducements

The first essential is that national funds be made available to doctors who wish to form group practices The sum of £100 000 per year which has been set aside from the Danckwerts award is quite inadequate As the N H S is at present organised it is hopeless to expect many doctors themselves to raise capital to establish a group practice and present banking controls make it difficult even for the few who may wish to do so to find the money

The capital cost of a medical centre which I have given above, is as low as possible and an enlightened Ministry or Government, taking a long term view should look beyond this and aim at a construction (as distinct from a conversion) programme To encourage group practice and to develop medical centres throughout the country I suggest the following scale of grants

Size of group	*Capital grant*
Five-doctor	£10 000
Four-doctor	£7500
Three-doctor	£5000
Two-doctor	£2500
Single doctor (where no alternative is possible)	£1000

---

e two previous articles appeared on July 4 and Sept 19

These grants, of course, must be tied to specific conditions, which will improve medical care, preserve professional autonomy, and yet permit the control necessary for spending public money Some such conditions as the following might be suitable

1 That groups will limit themselves to a maximum of 2500 patients per doctor
2 That an additional sum not less than half the capital grant will be contributed by the doctors—i e, every Government £1 will be matched by 10s from the group
3 The doctors will agree to
   (a) Give a twenty four hour service
   (b) Keep unit or family records on forms provided.
   (c) Make these records available for bona fide research
   (d) Allow medical auditing by regional specialists
   (e) Take a minimum of two weeks' leave for postgraduate study annually
4 All capitation fees will be paid to the group and not to member doctors
5 The group will enter into a legally drawn-up partnership agreeing that
   (a) A group leader shall be named
   (b) The minimum share of the most junior partner will be not less than £750 p a and he will have the right of resignation, may be dismissed, or given full term partnership status at the end of twelve months
   (c) An annual sum of not less than £100 per doctor will be set aside for postgraduate studies, medical society memberships, &c
   (d) The maximum amount of work permissible outside the group (defined in terms of time or earning) will be set out
   (e) All professional earnings from extra group sources will be pooled and distributed in terms of the partnership agreement

Provided these general conditions are met, the agreement would permit payments in various ways—e g, to the group leader for administrative responsibilities, or to a group member assuming special responsibilities for, say, obstetrics or research

In my earlier articles I discussed the reasons for all these proposals, except the proposal that the doctors should themselves contribute half the capital I have two reasons for proposing this To be a shareholder in an enterprise is often considered an incentive to strive for success Again, these contributions will relieve the strain on the Exchequer The doctor's share should revert to the Government (by purchase on retirement or death of the original group members), otherwise a form of sale of practices would be reintroduced

There are certain obvious objections to this, as to almost any other, plan for financing medical services For example, why should one generation of doctors bear the burden of financing, even in part, facilities for future generations? On the scheme suggested above this is in effect what would happen, and, unless some form of sale of practices is to be reintroduced, there seems to be no alternative Naturally the doctors who contribute funds to the construction of medical centres should receive a fair rate of interest on their money, which should be regarded by them and by the Government as any other national loan investment There is no reason at all why one generation of doctors should subsidise another

Perhaps, in these circumstances, the reintroduction of "sale of practices" would not be so bad, provided it was clearly established that it was sale of material facilities and not sale of "good will," as in the past However, there would be many complications to any such scheme For example, a medical centre built in 1953 would be more likely to depreciate than to appreciate by, say, 1963 (if the "good will" factor is excluded), and the doctor making the initial investment would find it difficult to recover his money, let alone enjoy a reasonable margin of profit on the capital he had had tied up for ten years It may, however, be possible to work out some satisfactory scheme along these lines and so perpetuate the private-enterprise element, which some consider a [illegible] to better work and greater effort

Another plan would be for a local authority the doctor members) to contribute half (or an fraction) of the capital, and this alternative would much to recommend it Thus for the price of W Down the London County Council could have some fifty basic centres housing 250 doctors and approximately 625,000 people The value of this of joint central and local government enterprise has proved by the results of the Hill Burton G Hospitals Act in the United States Against such enterprise in this country is the general mistrust of local authorities and his not al less fear of being dominated by them But, if this method of financing the centres could two branches of medical service

But maintenance costs as well as capital costs be instruments of policy It is not wise, in an to take maintenance costs into account, to capitation allowance, pay excessive salaries, or fee-for-service schedule which is impossible to The onus should not be on doctors, either indiv collectively, to limit their net incomes in order to the quality of the medical care they can offer would now suggest that the research-worker should left to buy his own equipment or the professor to the salary of his own teaching assistants? To would destroy the foundations of research and as it is at present undermining the foundations of practice At least the salaries of all medical should be met from national funds and all record material should be provided

I estimate the annual cost of salaries of the five-doctor group at £2100 With the addition record-keeping materials, a subsidy of, say, £2500 cover most of the running costs of the group would of course be free to engage additional staff. a subsidy would reduce the expenses of the group approximately a quarter of their gross takings, if maximum number of patients per doctor was fixed 2500, and would compensate for the drop in income this limitation would cause The maximum net per doctor, from capitation fees alone, would then about £2000

Once the arrangements for setting up the completed, the autonomy of the group would be sanct The Government's final administrative would end with the signing of the partnership agree

Cost to the Nation

For a population of 50 million people, in which doctor looked after 2500 patients, 4000 five doctor (or the equivalent in smaller groups) would be ne If all the general practitioners of the country decide join the scheme at one fell swoop, the central Gov would have to put down £40 million (£10,000 per cen The doctors would have also to be paid off for shares, amounting to £20 million, over the next or thirty years If these shares were held by authorities, they would not of course have to repurchased with central funds

However, it is much more probable that, even with inducements suggested, the rate of entry into practice would be slow It could be planned on, or regulated and budgeted for, an eight year period example This would mean £5 million in capital per annum for eight years

If a subsidy towards running costs of £2500 per per five doctor group were offered, and there was equal growth of groups over an eight-year period cost in the first year would be £1¼ million, rising by same amount each year to a total of £10 million.

When the scheme was in full operation, practitioner services (in terms of doctors' incom capitation fees—and direct subsidy to running co group practices) would cost £60 million per annum.

ns of the total N H S budget and the importance of a d general practitioner service this would not be proportionate.

Administrative Problems

'he biggest initial problem would be to set up satis ory machinery for approving grants Before any nts could be made, the Ministry of Health (or a fessional committee appointed by it) would first have approve the site premises (plans for conversion or struction) and partnership agreements This would d both central and regional bodies able to give sound ice on architecture legal aspects and organisation and ling

ll registered doctors must be eligible to enter a group ctice and apply for grants there could be none of the ding and choosing among doctors to which academic research bodies are inclined when they contemplate ficial developments along these lines

riority should be given to groups of the size most able for local conditions That is to say a five tor group should be given priority over a four-doctor *hree-doctor group in a densely populated urban area* not necessarily over a three-doctor or two doctor up in a village

fter a trial year a group which wanted to expand its nbership (up to a maximum of five) should be eligible an additional capital grant and staffing allowance up but not exceeding, the sum available for the larger up

nce minimum standards were agreed, the adminis ion of the scheme would be a big but not impossible k and one which would grow less with the years of the greatest initial difficulties would be to ourage doctors to form groups of a suitable size for re would be a natural tendency to try to form among nds groups of two or three rather than five As ucements five-doctor groups could be offered priority ger grants, and more staff

nce they have accepted the conditions set out above groups would be completely autonomous. The lical auditing of work within the groups would be le on a professional (as distinct from Ministerial) is, as it is in the better hospitals. Its purpose would not to police and discipline the weaker brethren but advise and help them

he personal or family record card (supplied by the istry) should be standardised so that it could be used research *But it should be designed by general* ctitioners to meet the needs of general practitioners, l not by Ministry officials whose chief interest is ninistrative ease and technique

General Comments

he financial and administrative programme I have lined is revolutionary But it is a revolution which ld take place within the present framework of the H.S It does not disturb established *traditions*—e.g capitation method of payment—and it would remove ny of the more reasonable and substantial worries of eral practitioners Capital needed would be no ater than the sum conceded to general practitioners retrospective payment by the Danckwerts award.

scheme of this kind calls for a more flexible attitude administration It calls for a renunciation of the gue dreams of 1948 of health centres as a possible ans of integrating the preventive and curative services l at the same time compensating local authorities for ir hospitals. But more than anything else it means ting the patient first, above and beyond any con erations of administration or concessions to the tors in the name of political harmony

n the positive side, from where the doctor sits, basic mp practice offers the general practitioner the chance to regain his prestige by improving his performance and the opportunity to become in reality all he is supposed to be in theory

The hard headed financial expert might well ask what can it offer in saving of cash apart from the invaluable but intangible benefits of improving general practice ? It is impossible to give a clear-cut answer to this question but two points are worth considering :

(a) *The better general practice becomes, the less work* will fall on the hospitals, where the care of patients is most expensive

(b) A large proportion of N H.S. expenditure is for drugs and medicines Overprescribing is an index of unsatisfactory medical care particularly at the level of general practice, and there is no administrative way of controlling this properly Even the largest American voluntary insurance schemes with rigid administrative controls and limited scope, cannot afford to offer drug benefits. The man who signs the prescription and no-one else regulates the size of the drug bill of the nation Better methods of general practice particularly methods which allow the doctor more time to be with his patients, would probably reduce the rate of prescribing

I believe that the saving in the drug bill which would follow the introduction of basic group practice would more than meet the cost of the capital grants and subsidies offered under the scheme

Again without group practice and all that it implies general practice research can never return the dividends of which it is capable

In the narrow sense, the N H S is no longer a political issue It is accepted by the people and by all political parties It is from the doctors that the lead must now come, and it is to be hoped that the new College of General *Practitioners and other professional organisations will* outgrow their fear of mixing politics with medicine and recognise that medical economics and organisation are the instruments of policy and mean more than the size of doctors incomes and the capitation fee The finance and the organisation of general practice are now the politics of medicine in Great Britain

HOW CONSTANT IS THE I Q ?

A. D B Clarke
Ph.D Lond
SENIOR PSYCHOLOGIST

A M Clarke
Ph.D Lond
PSYCHOLOGIST

DEPARTMENT OF PSYCHOLOGY THE MANOR HOSPITAL,
EPSOM SURREY

Since the early years of this century intelligence tests have been used as measures of general intellectual capacity and an immense body of published work has grown up around the subject Nowadays the intelligence quotient (I Q) is widely employed in educational selec tion and clinical procedures and there is no doubt that *intelligence tests provide* a method more valid than subjective or clinical judgment in assessing a person s intellectual level Not only is the I Q used as an estimate of a person's present intellectual status but the addi tional assumption has developed that this remains sufficiently constant during the life of the individual for fairly accurate predictions to be made about his future ability In other words, a person s intelligence at for example the age of 5 would be the same relative to others of his age-group at later ages ; thus the young genius would always be a genius the average child would always be average, and the defective would remain defective Such are the implications of a belief in a constant I Q a belief which within broad limits seems to be in accord with common observation Nevertheless, how broad such limits may be is of great importance at present when the I Q is so widely used in selection (e g , of school-children at the age of 11), and in this paper we consider this point

Mental Growth in Normal People

In the United States there have been many studies of I Q constancy which have as yet received little publicity in this country It is not our aim to provide a comprehensive bibliography, but the few references given will enable the interested reader to trace several hundred researches bearing on the problem

Nemzek (1933) and Thorndike (1940) summarise in all 359 studies carried out before 1940, and such researches show consistently that (*a*) the predictive value of the I Q (as measured by test retest correlation) decreases as the interval between the tests lengthens, and, as a corollary, (*b*) although the group or population average may not alter greatly, there will be considerable change of status of some individuals within that group (subsequent retests showing that to varying extents some subjects increase in I Q, some decrease, and some remain constant), and (*c*) mental tests given to children during the preschool years have usually little predictive value, and that assessments during infancy have no relationship with later status (except of course in such clear cut clinical entities as mongolism, microcephaly, and the like)

To illustrate the first two conclusions, the practical implications of commonly observed test-retest correlations may be considered Reviews by Nemzek (1933), Thorndike (1933), and Thorndike (1940) have shown that retest correlations are rarely as high as 0 95, and that on *immediate* retest the most probable value is 0 9

Shapiro (1951) demonstrates the implications of this second finding as follows "Let us assume that we have a test with a test-retest correlation of 0 9 and a standard deviation of 16 These data mean that, out of every 3 children obtaining an average score of 100, one would obtain a retest score above 107 or below 93 On the basis of the same data, out of every 10 children obtaining an average score on the first test, one child would obtain a score above 112 or below 88 on the second test (These illustrations assume that no learning has taken place)"

I Q changes may, of course, occur for a number of reasons errors of measurement as well as genuine alterations in the rate of intellectual growth may account jointly or separately for lack of perfect reliability

Over time-intervals of several years, test retest correlations are usually much lower than 0 9 Honzik et al (1948) found a retest correlation of about 0 6 for a time interval of 12 years, after following up a representative sample of urban children from infancy to the age of 18 years

They tested over 150 children at the ages of 6 and 18, and found that the I Q s of 58% changed 15 or more points, the I Q s of 35% changed 20 or more points, and the I Q s of 9% changed 30 or more points In only 15% of cases was the change 9 points or less Individual I Q constancy over this period was thus the exception rather than the rule The group averages, on the other hand, showed a maximum shift in I Q, over this period, of only 5 points The maximum I Q change for any individual was 50 points Similarly, Hilden (1949) who is in process of studying the intellectual growth of 100 children, has reported findings on 30 of these examined from early childhood to late adolescence In this small sample, too, individual variability in I Q was often found

Dearborn and Rothney (1941) have reported findings from the important Harvard Growth Study in which both mental and physical development in children were investigated over many years, their book gives results from many different researches on several hundred children They conclude that "prediction of growth at various ages is extremely hazardous, but is particularly so during the period of adolescence marked variability in individual growth curves appear throughout the course of the growth period The principle of individual variability goes right to the root of such problems as constancy of the I Q We have established the fact that variability rather than consistency of growth is the rule, that prediction except for average of groups is extremely hazardous "

To illustrate conclusion (*c*), namely that in the preschool years have little predi Honzik et al can again be cited

Tests at 21 months correlate less than 0 1 with at the age of 18 years Similarly, Bayley (1940) mental scores derived from tests at 7, 8, and 9 correlating highly with scores a few months later, relationship in the region of zero with all after the age of 30 months Indeed, in at least three quoted by Jones (1946), small negative correlations found between intelligence scores in infancy and test in later life As age increases, however, so does the with later intellectual status Thus, Bayley (1949) that for 27 children tested from infancy onwards, the tions with the test score at the age of 18 years positive from the age of 2, and by the age of 4 had 0 52

From the wealth of available data it is clear the general population, the concept of a rigidly I Q is contradicted by the facts, I Q constancy long periods of time during the years of mental is the exception rather than the rule Moreover, conclusion is based on the findings of researches in individual rather than group tests were used most part, all that has been said applies with greater force to group tests (widely used for which are in general less satisfactory than intelligence tests

Intellectual Changes in Mental Defectives

The general thesis advanced above can be illustrated by some work we have done recen mental defectives This has led us to ask permanent is intellectual subnormality? Is defective, always a defective' true?"

In the past there have been several studies exclusively of feeble-minded, non-organic d which I Q changes—often large—have been Such writers as Burt (1947), McKay (1942), (1945), Spaulding (1946), Sarason (1949), and (1949) have described I Q increments, some as 43 points These investigators, however, while various hypothetical explanations for the chan intellectual level which they demonstrate, rarely submit their hypotheses to experimental proof same criticism can be applied to the studies of already quoted.

We have retested with the Wechsler test over 100 adolescent and adult certified de The population from which they were drawn has been described by MacMahon (1952) As a routine intelligence testing we observed that patients who had been examined a year or more with the same test showed large I Q increments, we planned a research to elucidate these I Q and to determine the frequency of their occurrence

The main experiment entailed the retesting of 59 subjects after an average of 27 months had elapsed the original test, 27 of these patients increased their by 8 points or more, 17 by 10 points or more, and points or more, the maximum increment being 25 The remaining 32 patients showed small increases or Increments were general throughout the sub-tests Wechsler intelligence scale, and were not merely conf a few of these The test-retest correlation was 0·90

In order to determine the maximal effect of test tice, errors of measurement, and underestimation at time of the first test (since many certified feeble-m patients are emotionally unstable their intelligence occasionally be underestimated when they are a control group of 29 mentally subnormal mostly new admissions to the Manor Hospital hed with the main group for initial I Q and age was retested after a short time interval (average aths)

---

* This study has already been reported to meetings of the Deficiency Section of the Royal Medico Psychological tion (Nov 5 1952) and of the British Psychological (April 13 1953)

retest these subjects showed an average increase of ats, the majority showing changes between plus and 4 points only 6 had increments of 8 points or more aly 1 of these had an increment of over 10 points (13) The distribution of these changes may be seen in I The control group data, therefore indicate that the o increment of 4 points upon retest represents the o maximal effect of test practice *errors of measurement*, itial underestimation In terms of test retest correla 0·94—the reliability of the test is quite high on this ation

ral hypotheses were advanced to account for the se in I Q shown by the members of the main group of these hypotheses was critically examined, but cases but one the evidence was such that they o be rejected The exception was that there was ng relationship between very adverse early home tions and subsequent I Q increases Twelve clearly d criteria of adverse home conditions were formu —N.S.P C C intervention orders appointing some- a 'fit person'' to have charge of the child, parental de antagonistic towards the child home conditions bad home dirty and neglected child considerably ted, no fixed abode irregular school attendance due rental neglect, gross poverty deficiency diseases, found begging or wandering and parents or sibs minal records. These were applied to the 59 case ies under consideration, and the presence of two ore of these somewhat overlapping criteria was as clearly indicating very bad home circumstances s found that those who had been subjected to such se early environments were mainly those who made I Q increases. An external investigator (Dr J Tizard Medical Research Council s Unit for Research in ational Adaptation) who had no knowledge of either atients or their test-scores, independently analysed ase histories he agreed with our assessments of conditions in 55 of the 59 cases in the remaining es his rating was accepted as final Evidence of bad home conditions was found in 25 case histories in the remaining 34 there was either no evidence lly adverse conditions or a complete lack of data ling early home life, or (in only 6 cases) clear nce of a good home Tables I and II show the results of the investigation

difference between the gains made by the ' very home'' group and the remainder is significant d the 0·1% level which shows very clearly the association between early adverse environment Q increase many years later It is consistent with nding to suggest that the environment which is *antagonistic towards the child* retards mental opment for many years. Later however after al from such conditions this retardation begins le and I Q increments occur often at ages when l growth is commonly assumed to have ceased

rospective validation such as has been described with it the possibility of error as a result of e relationships in the records of those investigated. s necessary therefore to ascertain whether the criteria of bad homes were equally effective in predicting I Q changes as they had been in discriminating retrospectively

TABLE I—DISTRIBUTION OF I Q CHANGES

ange (points)	Very bad homes (25 cases)		Remainder (34 cases)		Control group (29 cases)	
	No.	%	No	%	No	%
o 6	1	4 } 100	8	24 } 100	4	14 } 100
o + 7	6	24	17	50	19	66
r more	18	72	9	26	6	21
r more	12	48	5	15	1	3
r more	7	28	0		0	
	1	4	0		0	

TABLE II—CHANGES BETWEEN TEST AND RETEST IN FULL SCALE I Q POINTS

—	Very bad homes (25 cases)	Remainder (34 cases)	Total group (59 cases)
Mean change	+ 9·7	+ 4·1	+ 6·5
Standard deviation	6·3	4·9	6·2

t = 3·86 significant beyond 0·1% level
I Q range at first test = 36–98 mean = 66·2; S.D = 11
I Q range at retest = 49–97 mean = 72·7 S.D = 12·4
Age range at retest = 14–50 years mean = 23·5; S.D = 8·1 years. (Only 9 patients were aged over 30.)
Period between test and retest: mean = 26·0 months S.D = 6 *months*
Range of I.Q changes − 7 to + 25 I.Q points.

There remained at the hospital only about 20 *patients* who had been tested two years before and who had not already been retested for the various experiments included in the research from these 6 cases were selected whose records clearly indicated adverse home conditions, and *a further 6 were found who had come from homes which seemed* unlikely to have been very bad. Increments were predicted in *the former* but not in the *latter* and it was only after definite predictions had been made that retests were undertaken The changes in I Q points for those for whom increments had been predicted were + 14 + 9 + 10 + 10 + 4 + 5 average + 8·7 points the changes for those for whom *increments were not predicted were:* − 5 − 2, + 7 − 1 + 4 average + 0·6.

It will be noted that on this very small group the criteria show some predictive value it would, of course, be desirable that this finding should be checked on a larger group and indepedently as was the retrospective validation

The I Q changes in this investigation were largely in the upward direction whereas in some researches already quoted the variability was equal in both directions This, however is probably the effect of the very adverse backgrounds of the certified feeble minded and it is not suggested that the factor shown to be associated with I.Q changes in this research is necessarily the only one underlying changes in general Other investigators have suggested both this factor and others in relation to the problem of I Q inconstancy As already noted however these hypotheses seem never to be carried to the stage of experimental validation

The results show clearly that intellectual retardation among such deprived people as have been studied here is not necessarily a permanent and irreversible condition Obviously too the increases demonstrated over a period of two years will not represent, in most cases the total change which the invididual has already made or will make in the future As Honzik et al. (1949) point out some subjects show consistent trends in I Q changes over a long period

Conclusions

It is evident from the work of many different investigators that, group averages apart, considerable changes in intellectual level may take place during the course of individual development and that the question is not so much Is the I Q constant ? but rather How constant is it ? As Honzik et al. put it

> Whereas the results for the groups suggest mental test stability between 6 and 18 years, the observed fluctuations in the scores of individual children indicate the need for the utmost caution in the predictive use of a single test-score or even two such scores This finding seems to be of special importance since many plans for individual children are made by schools juvenile courts, and mental hygiene clinics on the basis of a single mental test score "

The fact that all longitudinal studies of intellectual growth show a decline in predictive ability of the I Q with increase of time implies change in individuals

The I Q, percentile grade, or standard score must be regarded as an objective estimate of a person's present intellectual status, and it is certainly better (even for predictive purposes) than subjective judgment or unstandardised examinations When we use the I Q for prediction, however, we must realise that errors are inevitable, and that these errors may have far-reaching and serious consequences for individuals selected by the tests for particular purposes

The fact of I Q variability can no longer be disputed, and the evidence is rich in implications Let us consider merely one example it has been shown that a group of socially deprived, mentally subnormal people tend, when removed from adverse conditions, to advance towards intellectual normality Can such relatively spontaneous changes be accelerated and improved? These and many other related problems invite the psychological and psychiatric investigator to a clear field for research

We wish to thank Dr J F MacMahon, physician superintendent of the Manor Hospital, for his help and encouragement during this research, Mr M B Shapiro, senior lecturer, in the psychology department of the Maudsley Hospital, for stimulating suggestions and criticisms, Dr J Tizard for help in an essential part of the experiment, Mr A Ehrenberg, of the statistical laboratory of the Maudsley Hospital, for useful advice, and Mr G J F Singleton for the statistical computations

SPECIALISATION AT SIXTEEN

SPEAKING at the inauguration of the new session at Westminster Medical School on Oct 12, Mr H E Harding, F R C S, the dean, spoke strongly of the effect of the changed requirements for matriculation at London University

"In the past," he said, "a student matriculated at about 16 years with credit passes in a minimum of five subjects and thereafter spent two years working for a Higher Certificate in subjects of his choice and aptitude, knowing that he had a place for medicine The new requirements are six ordinary-level passes and at a subsequent examination two advanced level passes The results of these examinations are available in most cases only a week or two before entry to the University course and our final entries cannot be determined until this date We have been very concerned that some of the best candidates on general grounds have failed to satisfy these requirements and a last-minute revision of acceptances has been necessary Not a single applicant offered advanced level subjects in English language or literature—in fact most had become scientific specialists from the age of 16 This drift from the humanities, our language and our literature, is to be deplored, for they provide the only fundamental background for a good doctor, who must have the gift of simple and lucid expression and a wide understanding of people What may be a good background for a scientist is not enough for a good doctor and I therefore condemn these changes wholeheartedly"

Mr Harding mentioned that in the past year Westminster students had derived great clinical advantages from a period of two weeks' resident study at St Stephen's Hospital, he thanked the staffs of St Stephen's and of St Helier Hospital for the enthusiasm they showed in teaching the students.

A change made during the year had been the
of the children's department to Vincent Square
with over 100 beds should be able to provide
pediatrics teaching better than in any other
hospital" The number of students at Westminster
steady at about 220, and applications from
candidates had been considered for 65 places.

ɪRAX IN FACTORY HANDLING SUN DRIED BONES

-dried crushed bones from India and Pakistan ɜ raw materials in a chemical factory engaged in the ɪacture of fertilisers, glue and gelatin The bones, are crushed to sizes varying from 0 5 cm to 5 cm ported in canvas sacks each holding about 1½ cwt ɜs of anthrax occur among the workers whose ɪt is to stack the bones or otherwise to handle the before the chemical treatment begins. This cal process consists in contact with mineral acids for days, followed by treatment with lime &c long time The resulting fluid is heated and rated under reduced pressure to supply phosphates and gelatin *It is not believed that anthrax or spores would remain viable throughout such* ess.

m 1947 to 1952 inclusive 13 cases of anthrax ed in the workers handling the bones and the sacks. 4th case was in a man who visited the factory to o empty sacks in his lorry a few days later he ped anthrax No cases occurred in any other ɪf the factory and anthrax was confined to those andled the sacks and the sharp crushed dried bones f the 14 cases the diagnosis was confirmed bacterio lly In the other 5 treatment was begun before ıens were taken and it was thought undesirable ɪurb the lesion unduly to get a satisfactory specimen lture

ı laboratory examined thirty samples of bone, three ɪt, four of sacking and two of dried sinews from ıctory Anthrax bacilli were isolated by animal ation from two samples of bone and one of sacking

DISCUSSION

Wales most cases of anthrax in man can be traced ıtact with infected sun-dried crushed bones from ar East As might be expected, the anthrax ıts as a malignant pustule among those workers ɪarry the sacks of sharp crushed bones, and no have appeared in other parts of the factory where ɪnes are chemically treated. In 13 of 14 cases the was on the face or the neck

lff and Heimann (1951) showed that in the United ı of America most cases of malignant pustule could aced to materials imported from the Far East wool was the source of the infection it was not ɪool from Australia but coarse wool from the Far ıused in the manufacture of carpets. When hides the source of the infection they were almost always des from India and Pakistan. Wolff and Heimann tated that in 1947 a million animals died of anthrax ın Anthrax is also very common among animals ı Far East

ndustrial anthrax in Great Britain the origin of the ial seems to be all important Crushed bones are ted into Britain from many countries. The ıts with anthrax mentioned here handled crushed ried bones from India and Pakistan in large ities, and anthrax bacilli were demonstrated in ɪes of these bones *Of the 14 cases reported here* ı was not employed in the factory but was a lorry who removed empty sacks from the factory ɪlar incident was reported by Holgate and Holman)

SUMMARY

cases of malignant pustule occurred in factory ɪrs who handled sun-dried bones from the Far East. ɪther case was in a lorry driver who took away from actory empty sacks which had contained such

We wish to thank Prof J Gough and Dr Scott Thomson for advice and encouragement in the preparation of this paper

Control of Food-poisoning

Following the recent outbreak of food poisoning in Wakefield,[1] *a recommendation from the city's health* committee is to be placed before the city council[2] It asks that strong representations be made to the Ministry of Health to provide legislation that will enable a medical officer of health to close premises where persons suspected of being carriers are engaged in preparing or handling food The shop involved in the Wakefield outbreak did in fact close voluntarily for two weeks but under existing regulations the medical officer of health's powers are limited to the suspension of employees known to be carriers.

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ended Oct 10 (40th week of the year) were (previous week in parentheses): paralytic, 107 (79), non paralytic 69 (78); total 176 (157)

The following table compares this year up to and including the 40th week with the preceding six years:

Year	*Total cases up to and including 40th week*	*Cases in 40th week*
1947	7093	429
1948	1537	66
1949	4023	376
1950	6711	363
1951	2301	96
1952	3483	166
1953	4256	176

There has been an increase of 28 in paralytic cases and a reduction of 9 in the non paralytic cases as compared with the previous week. The weekly notifications at this time of the year are often a little erratic and there is no reason to believe that the reduction in notifications will not be resumed very shortly

Statistics for England and Wales

Provisional figures for England and Wales published[3] by the Registrar-General show that in the quarter ended June 30 1953 the birth rate was the highest for two years. There were 179 404 births registered during the quarter, representing a birth-rate of 16 4 per 1000 population—the highest for any quarter since the second quarter of 1951 There were 114,538 deaths registered in the quarter—a rate of 10 5 per 1000 population which is the lowest rate for a June quarter since 1948 There were 4441 deaths of children under one year of age giving a rate of 25·0 per 1000 related live births. The 4199 stillbirths registered represent 22·0 per 1000 of the total live and stillbirths.

Provisional figures[4] for the third quarter of this year show that the birth rate was higher and the stillbirth and infant mortality rates lower than the rates for the corresponding quarter of 1952 Live births registered numbered 172 976 representing a rate of 15·6 per 1000 population Deaths registered numbered 98,588, giving a rate of 8 9 per 1000 population Deaths of children under one year of age totalled 3832 or 22 2 per 1000 related live births. There were 3709 stillbirths registered—a rate of 21·0 per 1000 total live and still births.

In England Now

A Running Commentary by Peripatetic Correspondents

AFTER a long drive through the parkland and a short approach through formal gardens of juniper and cypress, I was met at the door by Saunders, the butler, who peeled off my coat and took my hat and gloves. I was allowed to keep my stethoscope and book of forms.

I was asked to wait for a few moments, and was glad of the time to inspect the Great Hall with its carved stone fireplace, the oaken screen supporting the minstrels' gallery, the staircase with its wide and gentle tread, and the emblazoned angels peering with irreproachable piety from the hammer beams of the old timbered ceiling. The evening sun streamed in through the great mullioned windows, lancet and oriel, in a thousand fragments of tinctured light, and it was through this misty mosaic of colour that her ladyship descended with a dignity and measure which belonged to more spacious days.

She conducted me along the gallery into a bedroom which, I reflected, must be twice the area of my house and surgery put together. His lordship was enshrined in a four-poster, inhaling menthol and buttressed by a cloud of pillows. From the portraits on the panelled walls, ancestral faces regarded him, some with disfavour, some with dispassion—none with encouragement. Our consultation, including an elaborate clinical examination, took twenty minutes. The diagnosis was flu.

With customary graciousness, her ladyship accompanied me downstairs to the entrance hall. I bade her be of good cheer, for there was little cause for alarm. I felt, and hoped I looked, wise and kind and rather medieval. I was about to drive away, when Saunders hurried down the steps, bearing a silver salver and upon it a paper. "His lordship has just noticed, sir, that you have forgotten to sign his First Certificate."

* * *

What magnificent stuff the Widdicombe File is giving us these days. "ORGS." Absolutely divine. I should think the article will be wonderful too, I haven't actually read that yet. I can't stop thinking about the title. What *can* it mean?

Orgs at last, thought the traveller, gazing from the hill at the tiny town nestling in the marshes below. Orgs, the pearl of Provence as the oyster-hating King René had named it. Orgs, one of the smallest walled cities in the world and the sole to have a wall with the purpose of keeping the inhabitants in. Before these walls, Axel, brother of Charles Martel, had slain 375,000 Saracens[1] with an armoured flit gun without any noticeable benefit. A pall of blue smoke hung over one building in the centre of the town. The Grand Hôtel d'Orgs, smiled the traveller tightening his belt in anticipation of supper. The Grand Hôtel d'Orgs, the solitary hotel in the *Guide Michelin* to have four exclamation marks after it. He strolled down the hill rather nauseated.

Orgs, exclaimed the wickedest man in the world, really what will they do next? Alastair Crowley would have been aghast. It was bad enough when Aldous flippantly referred to orgy-porgies in *Brave New World*, but these people go too far. The ancients would have been shocked. "Is there an org on at the palace tonight, Nero?" or "Splendid org at your place last night, Messina." As for the French masters, they would simply have shuddered. "The Marquis de Sade requests the horror of your company at an org in the château tonight." Really he would go round and see the editor. He would carve it on his chest with an amethyst-tipped lancet (oh, justice), saying through clenched teeth "this will teach you to use abbreviations."

"Orgs, sir," stuttered the keen young houseman, "I think it's Orgs, sir." "This seems to be one of the many conditions newly arisen since I was a registrar," said the surgeon. "Whatever is it?" "Why, sir, Orgs is an occupational disease of cinema organists. The mighty Wurlitzer first described it. It's a state of confusion in the motor cortex, due to the fact that they have to play arpeggios with both hands, pull out the stops, switch on the whistles, bagpipes, and drums, bounce up and down on those wooden both feet, and watch for spelling mistakes slides. Ultimately they do it all the time and, can imagine, they get terrible indigestion." The surgeon threw a sponge holder at the and shouted "Orgs has set in."

I'm looking forward immensely to readin

John (rising four) and I have got a new machine on which we do our sums. We have owned one, but never a machine that electricity nor one with so many buttons. It of 1's, 2's, 3's, &c, for adding or taking away, row of buttons that show an impetuous start multiplication. It will give us an answer figures though we don't usually want all rate it almost as high as a cash register. (" you have today, Sir? Rice is nice and Concealed in it are unsuspected depths of count tion. Clear the registers and take away 1 from What's the answer? At school it may be minus on our machine it is quite plainly 9999999999. This result reduces John to helpless laughter cannot press another button for at least ten. It is not, however, his favourite sum, which centres round the number 6, admittedly a good number, usually honest and dependable. He multiply 6666666666 by 6666666666. Curiously the result is 44444444435555555556 which has attractive symmetry. My own favourite is to 355 by 113. The machine works the answer itself, and returns to the starting-point in haste. There is just time to gulp a cup of it is not too hot. The result is 3 141592920, to 6 places of decimals; we have tried a lot fractions but they are all quite hopeless. T us that π is not only irrational but tran- we haven't got as far as that yet. Alt wonderful machine and it lacks only one bell that rings when we do the sum right.

I approbate that mother who wrote to the mistress protesting against Maggie being taught logy. "It don't do her no good, and only rude." I hold that to attempt to educate the by health talks is to do them disservice. It all very well. Teach people to be clean, to their teeth, to eat, drink, and smoke in and to take regular open-air exercise. But to tell to look for the early signs and symptoms of disease? I think not.

We ourselves are bad enough in our of subjective occurrences. Which of us has recognise in himself heart-disease or malignant I have always supposed myself to be relatively this foible. But last week revealed that I am no than my betters.

Weakness of my right hand and various sensations in the upper limb set me on the differential diagnosis. Was I conscious of some tory difference, could I detect dissociated or wasting of the thenar muscles? Attempts at investigation are conspicuously clumsy and attracted attention. "What on earth are you asked she who insists on knowing everything facedly I described my symptoms and the fears had occasioned. "Don't you think that bed-making for the first time at your age might something to do with it?" said she, who if she respect for such academic distinctions as M.D. successfully conceals it.

* * *

Overheard at an interview for a post of county of health in Ireland.

Member of Selection Board. "The League of Nations collect international epidemiological information, looks after it now?"

Candidate. "I don't know."

M.S.B. "But I've just told you."

Candidate. "Who?"

M.S.B. "That's right."

Letters to the Editor

STRIC RESECTION FOR HÆMORRHAGE

—In the search at operation for the cause of æmesis and melæna Mr Ferguson (Oct 10) like the limit drawn at laparotomy followed use of eye and hand on the outside of the viscera abnormality is found he advises a burst of activity form of passing through the motions of one's ite brand of partial gastrectomy in the hope sume that this shot-in-the-dark technique will he lesion in the bag I agree he will probably be or 8 or 9 patients out of 10 But what of the other ? *They may well bleed on* and one has seen it n, that a pretty partial gastrectomy was performed e bleeding ulcer was left behind

s by no means rare to find no external sign of an at laparotomy for gastroduodenal hæmorrhage *ect at gastrotomy one or more acute ulcers, from* ghth of an inch to one inch or larger in diameter be found These ulcers, in my experience are singly common in elderly women and are usually posterior wall in the middle third but sometimes may be found high on the lesser curve or may be in the fundus on the posterior wall Worse the bleeding points may be deeply down the num more than two inches from the pylorus e seen two such ulcers one being partnered by an gastric ulcer which at first was *thought to be the* of hæmorrhage the bleeding duodenal ulcer being overlooked and left in situ

strotomy, even duodenotomy if necessary are the ways of finding the exact site of trouble and so ing that the operation is not followed by continued ng Mr Ferguson does not care for gastrotomy it is not justified by the soiling and loss of blood alls and that the view inside is a poor one owing adherent blood-clot Perhaps we do gastrotomy fferent ways, for I find it helpful in locating the

stomach is lifted into the wound and towels placed it to prevent soiling An incision about four to six long is made along the middle of the anterior surface stomach *starting at the antrum* and usually stopping before the point is reached where the customary transsection is made The cut edges are grasped by Duval which reduce bleeding to a trifling trickle Large clots are cleared out by hand and large retractors of the or Deavers variety (not the sharp-edged Morris retractor cuts the mucosa) suction, and wet or dry swabs are a good light is focused into the lumen and the whole r of the stomach can be seen as clearly as if looking *ht into the inside of a barrel* A *finger is passed* into uodenum and if necessary both the remnant of the m and the pylorus may be cut through, and even the or wall of the duodenum may be incised for about one The view is magnificent, and is unobscured by blood If no source of bleeding is found the edges may be and safely sutured with no serious reduction of lumen. ilst the stomach and duodenum are open and no satis cause has been found it is still possible to make a search of the lumen using a sigmoidoscope to get down the duodenum Also jejunotomy can be done itroducing the sigmoidoscope The jejunum is folded the sigmoidoscope in concertina fashion an excellent of the mucosa being obtained A long bronchial sucker reat help in clearing the way

no ulcer is found after such methods and an œso eal source of bleeding has been excluded it is fair to do partial gastrectomy on an empirical I have *a personal preference* in these patients dding a vagotomy to partial gastrectomy perhaps more empirically

gree with Mr Ferguson that it is not safe to close bdomen without making an attempt to stop the ing but I prefer to avoid blind partial gastrectomy and to stick to the fundamental principle of surgery—adequate exposure of the lesion

Radcliffe Infirmary
Oxford.

G E MOLONEY

SIR,—Mr Ferguson draws attention to a very real problem of surgical management I agree that with the exclusion of external evidence of a gastric or intestinal lesion it is right to proceed with partial gastrectomy for bleeding without wasting time doing a gastrotomy I would like to add two points Firstly the surgeon should split open the stomach immediately it is removed and inspect it within Secondly if he finds no obvious erosive gastritis ulcer or other cause of hæmorrhage he must inspect the inside of the *remaining* gastric fundus

I have seen two patients in whom a very high peptic ulcer was missed by external palpation; and in both instances hæmorrhage persisted after partial gastrectomy and proved fatal In one case I was the assistant and was astonished to see at autopsy quite a large chronic ulcer high up on the splenic aspect In the second case I operated myself and the same thing happened At autopsy a shallow ulcer about 1 in in diameter was found close to the œsophageal junction on the posterior wall of the stomach The crater was traversed by a large artery which had bled from a longitudinal clean-cut slit. Even at autopsy when the gastric remnant was removed, this ulcer could not be felt externally I believe that, in each case the patient's life could have been saved if the gastric fundus had been inspected directly and the offending vessel dealt with from inside

From my own experience of the type of case discussed by Mr Ferguson, where a laparotomy has been considered necessary for severe bleeding I would strongly advocate *partial gastrectomy at any age*

Liverpool

JOHN A SHEPHERD

PAIN IN CHRONIC GASTIC ULCER

SIR,—Discussions on the relation of gastric ulcer to pain are hampered by the lack of a common viewpoint in psychology and medicine. Pain is always associated with pattern-changes in the vascular flow in the tissues and the cardiovascular system is as much an organ of pain as the brain is the organ of the mind Psychiatrical conditions can be discussed in terms of vascular flow[1] and incomprehensible titles such as The Internalized Mother as Harmful Food in Peptic Ulcer Patients[2] would invite study if the meanings the authors intended to convey were related to particular tissue ischæmias and hyperæmias and associated with frustrations and compulsions respectively

Acid kills cells, and amongst other changes, damaged cells become acid and acidify neighbouring cells—the primary origin of pain The central nervous system ensures instant sharing of the acidity by distant cells of the body (nerve impulses being equivalent to a transfer of hydrogen ions or acidity) thus saving the damaged cells from destruction where possible The part played by the vascular system is mainly a removal of acid metabolic products ischæmia increasing the acidity in any functioning tissue

Specific reflex pathways are mechanised by modifications of the cerebral synaptic resistances, which can be expressed in terms of local blood flow in the neuropil[1] The sensitisation of nerve-endings by tissue degeneration products *may be considered as a decrease of tissue* (synaptic) resistance with hyperæmia and congestion The protection of nerve-endings by mucus is an ischæmic insulation of the nerve-endings Tissue tension distorts the vascular network giving patchy ischæmia and hyper emia (cancrum oris without oedema is painless) Tissue acidity is a cause of dilation of blood vessels The cerebral patchy anæmia in melancholia is relieved in some cases by the vasodilating effects of electroconvulsive therapy, and the congestion of the motor cortex in general paralysis makes the patient happy—the two clinical conditions representing chronic pain and its opposite, respectively

---

[1] Pickworth F A New Outlook on Mental Diseases Bristol 195[illegible]
[2] Garma A *Int J Psycho-anal* 1953 34 102

There is therefore no need to choose between the "acid"[3] and the "inflammatory" hypotheses, since both are ultimately true, but expressed in different terms As Mr Kinsella shows in his reply[3] to Professor Pickering (Sept 19), to state the problem in terms of vascular flow does clarify in a general way the meaning of his article[4]

Birmingham F A PICKWORTH

"CHEMOTHERAPEUTIC AGENT" AND "ANTIBIOTIC"

SIR,—I read with interest Dr Glass's letter last week I found it desirable to suggest (Aug 29) a more exact literal definition of "chemotherapeutic agent" than that offered by Professor Waksman, but had not intended to imply that the literal interpretation is in use or should be used "Antibiotic" in its etymological sense refers to something "against life," and, as someone else has already asked, "Whose βιοσ is it?" To follow this line of thought, *aspirin could be described as an antibiotic*, for, if ingested in sufficient quantity, it destroys the life of man, but none would insist on such literal accuracy

Although the terms "antibiotic" and "chemotherapeutic agent" both have much more limited meaning than their etymology would suggest, it does appear from the correspondence that agreement has not yet been reached as to what exactly they should mean After all, this is what one should expect of terms recently coined, and, therefore, still evolving

Frodsham, Cheshire G S ERWIN

RESETTLEMENT OF DISABLED PERSONS

SIR,—Your annotation (Oct 10) is not only unfair but it demonstrates clearly the self sufficiency of some doctors which has in fact been one of the greatest difficulties in resettling the disabled The purpose of your annotation seems to have been a denial of any good that the Ministry of Labour and National Service might have done in recent years, and a belated recognition of the achievements of a few medical pioneers in the past You remind us of the report of the British Medical Association Committee on Fractures in *1935*, the Government inter departmental committee in 1939, the rehabilitation of miners in 1940, and a few other such activities In so far as I myself was partly or largely responsible for many of them I can the more readily ask what this has got to do with the endeavours of today Let us be rid of this complacency

The Ministry of Labour has tried hard to implement the proposals of these pioneers, and in so doing has never lost an opportunity of collaborating with the medical profession Of course there have been failures—who would have expected otherwise in a scheme of such magnitude? It is because this great social service (and whatever you may say it is still ahead of any similar service in any other country in the world) has shown defects in its first few years of trial that the medical committee and the National Advisory Council have persuaded the three Ministers concerned to re examine the position

But for you to write that "perhaps the findings of the present committee of inquiry may point the need for fuller recognition of the medical implications of disability" is *little less than arrogance* This has been the endeavour from the beginning, and if in this respect there has been failure it lies more with th profession than it does with the administration,

As a simple illustration of this, let me quote annotation, which refers to doctors who are because "they have been discouraged by its give effective help to those patients whom referred to it" Did these doctors really think duty was done when they had signed a form of Did they believe that nothing more was expected than to sign a name? In the interests of their the aid of the disablement rehabilitation office, the improvement of the service, why did they more about it?

I will not bother your readers with the success that has been achieved in nearly one disabled persons in Great Britain Neither will the mistakes of which we are all aware But I that every physician, surgeon, and general p should find out for himself how great a service being offered for disabled patients and ask only doctor should use the service intelligently, and improve it by thoughtful collaboration rather thoughtless criticism

PERIODIC MEDICAL OVERHAUL

-Dr Capel (Oct 10) ascribes to me surprise that
prehensive clinical examination failed to reveal
nt disease, and then, somewhat gratuitously
s to remind me that there is a stage in every
before which diagnosis is impossible and that
ill are many diseases which, however early they
eted are incurable
ently he has failed to appreciate that I described
xperiences as the text of my thesis in disparage
the claim advanced in favour of periodic overhauls
rly evidence of trouble may be discovered and
l. To illustrate the value of the periodic overhaul,
ances the investigation of such symptoms as
indigestion piles, bronchitis menorrhagia flat
d varicose veins—symptoms for which any sensible
would seek advice I must again point out that
ponents advise the overhaul *when well* (I repeat
les employed in my original contribution)
Capel concludes by advocating a course of instruc
help the individual to adjust himself to his
ment; to avoid over eating over drinking and
unhygienic habits and a bad mental approach
g domestic discord to learn about suitable
y and the evils resulting from lack of hobbies
sumably an indefinite number of similar matters
a very different thing from a medical overhaul
nmon sense health education which should receive
earted approbation although I am by no means
led that a doctor is the best choice for such

NE MEMBRANE IN THE NEONATAL LUNG

-We are grateful to Dr Claireaux (Oct 10)
onstrating the importance of hyaline membrane'
use of death in infants in this country but his
t of the theory that the membrane is produced
linised epithelial squames is I think unfortunate.
fants dying a few weeks after birth keratinised
keratinised squames are frequently found and
ccompanied by any reaction or hyaline membrane
squames can also be seen embedded in, but
from the hyaline deposits in hyaline membrane
in the newborn
results of Dr Claireaux's experiment with auto
mniotic debris are not necessarily related to the
disease indeed it would be surprising if any
ous hyaline material injected into the lung of
l not show a deposit or membrane production
of six animals thus injected
line membrane is found in the lungs in children
the newborn period dying from nephritis
tic heart-disease and some deformities of the
These membranes are virtually indistinguish
om those seen in the newborn and any theory
production of hyaline membrane in the newborn
, I think take these other similar membranes'
onsideration In the older group it is unlikely
he deposits are in any way related to inhaled
al and the most obvious common basis is some
nisation of vascular circulation within the lung
ewborn child sustains great physiological changes
monary circulation during the transference from
tal to alveolar oxygenation and it would seem likely that it is in these intrapulmonary vascular changes associated with birth that the prime factors leading to hyaline membrane production arise

Department of Pathology

THE WRONG BLOOD

Sir,—You may delegate administrative responsibility but if you divide it you invite chaos The pathologist must administer the blood bank hence he should supervise the chain of demand and supply between patient and blood bank even though the clinician may order and inject the blood The argument is reinforced when the clinicians are mostly part time and the pathologist full time

Study your problems with diligence,' ' look not for refuge to anyone beside yourself ' are maxims for a consultant and if the pathologist follows them, his advice and help will be valued Let him wriggle out of responsibility which is naturally his, and he will forfeit the respect of his colleagues In this country it has always been assumed—in contrast to the suggestion made in Dr Walther's letter last week—that clinical pathologists are concerned with clinical matters, not with techniques alone

Central Middlesex Hospital

George Discombe.

ACUTE ANURIA

Sir —In discussing the treatment of anuria your leading article of Aug 22 lays emphasis on the need to correct the water and electrolyte disturbance Thus your approach is essentially symptomatic, for these changes are *secondary* to the renal dysfunction It is to be regretted that the primary change in the kidney is so lightly touched upon

The reader is left with an impression that a depleted blood *volume* leads to anæmia of the kidney—though ischæmia has been its designation—and that this is responsible for the anuric state. This interpretation ascribes to the kidney a *passive* rôle which is readily denied by its failure to recover when the blood volume has been restored and still more emphatically by an assessment of the various factors that precipitate anuria *Among these Darmady*[1] *includes acute pancreatitis* emotional states head injury myelomatosis typhus fever Weil's disease pneumonia favism mushroom poisoning streptomycin burns, crush injury septic abortion and many other conditions not associated with a depleted volume of circulating blood In acute glomerulonephritis, which you cite as an occasional antecedent not only is there no reduction in blood volume, but renal ischæmia is also not evident. For Bradley[2] has shown in this disease that if the extraction rate of *p* aminohippuric acid (P A H) is concurrently determined the renal blood flow is found to be increased. Yet the increase in renal blood flow is associated with reduced glomerular filtration. Such an alteration in renal hæmodynamics cannot be explained by a passive change in the kidney for it proclaims an unequal distribution of vasomotor tone within the organ determining the blood flow through its components.

It may be that you are inclined to attach lessened significance to biochemical interpretations in this connection because the popular concept of urine production with which such data are correlated has been weakened by the researches of Platt,[3] Borst[4] Wirz[5] Brodsky and Rapoport,[6] and many others. Or because confidence in it has been shaken still further by the experiments of Harvey L. White[7] who on explanting the bladder base and sampling the ureteric outflow, found that partial compression of the renal artery of one side reduced the water and sodium output by 50% on that side without any detectable change in glomerular filtration rate or in tubular extraction Nevertheless you say that "cogent evidence has been brought against the idea that blood is diverted from cortex to medulla and juxta medullary glomeruli"—which means that you are prepared to attach greater importance to inferential biochemical data than to actual visual proof [8–13]

---

[7] White H L. *In* Bradley S F., Renal Function New York 1950; p 128

Lovgren's [14] experiments on the frightened cat have shown that adrenaline stimulation does provoke the Oxford mechanism, and they offered an explanation of the "afferent" and "efferent" glomerular spasm which has been held responsible for the alteration in renal hæmodynamics which adrenaline produces From this it would be reasonable to assume that diversion of renal blood flow comprises a series of stages dependent on progressive alteration of intravascular tone (Sophian [15 16]) and based on the underlying principle of critical closing and critical opening pressures (Burton [17]) The experiments of Van Slyke et al.[18] do not deny its occurrence, but rather suggest that the Trueta reflex mechanism may not be provoked if the stimulation is too gradual, even though it continues and destroys the subject On the other hand, the evidence derived from the experiments of Insull et al [19] cited by you are hardly acceptable, made as they were on well nigh moribund animals in which all trace of the vascular tone responsible for the reflex had long since disappeared The theory of maximal tubular clearances on which much of the "cogent" evidence has been founded, although brilliantly conceived, can hardly be considered final We are left to conclude that the visual evidence supporting the Trueta mechanism must far outweigh the inferred evidence, and that cortical ischæmia is accompanied by diversion of blood to the medulla

The catadromous fish (e g, salmon and eel) also offer evidence of renal shut-down on change of environment (Homer Smith [20 21]), this effect being seen when they move from fresh water to the sea Further, it has been shown experimentally that renal ischæmia of the Oxford pattern precedes acute cortical necrosis Franklin and Sophian,[22] demonstrated this by stimulating the renal nerve Also Hoff [12] has shown that long-continued electrical excitation of the cat's brain produces cortical ischæmia and medullary congestion in the kidney, leading to acute tubular necrosis

In citing Oliver [23] you have perhaps lost sight of the fact that many of his nephron dissections were performed on Shaw Dunn's original specimens Shaw Dunn and Montgomery [24] established that these anuric kidneys with cortical destruction displayed subcapsular, juxtamedullary, and medullary survival, but you say nothing of this evidence which supports the then unheard of Oxford mechanism, although you admit that ischæmia is responsible for the cortical damage Further histological evidence has been provided in particular by Solymoss,[25] De and Sengupta,[26] Borst,[27] and and extensively by Sheehan [28] in a review of post mortem material Sheehan has shown complete cortical necrosis the spasm affects the end of the arterial tree at a distance of 0·5-1 from the origin of the intralobular artery, which the survival of the juxtamedullary nephron indicates a vasomotor alteration and therefore a rôle for the kidney

Biopsy of the anuric organ, by punch or by exp supports the view that cortical ischæmia and m congestion are concomitant

The experiments (of Franklin and Sophian demonstrated the mediation of the nervous changes of intrarenal vascular tone (Hoff [1]) ability of the kidney to recover if the changes very advanced Evidence is also forthcoming rapid establishment of diuresis by certain t methods, that the tubular state is reversible e late on This has been demonstrated by Dérot peritoneal dialysis, by Vallery Radot [30] with transfusions, by Hingson [31] with conduction an reaching the lesser splanchnic level, by Chat with vitamin C and anti histamines, and by O and Spitzer [33] with paravertebral block In inte the effects of intraperitoneal dialysis and of transfusion, a rapid correction of the milieu is implied which is comparable to the physiological over of the catadromous fish in re-establishing function when resuming a fresh water habitat

The association of blocked tubules with fatal merits consideration The obstructing material to be a myohæmoglobin derivative But globin itself has been shown by Franklin [34] to diuresis In a normally functioning kidney th stance cannot be held responsible for the renal In fact, Yuile et al [35] found that a short period ischæmia was necessary for hæmoglobin casts produced in the rabbit, whilst Badenoch and Dar have shown that, in rabbits, mechanical reduction renal circulation for 90 minutes, together with of stroma free hæmoglobin, causes a higher than either procedure alone It therefore seem tubal blockage of this type implies a preceding ischæmia (In cases of incompatible transfu early accompanying anoxæmia could have the renal shut down, whilst in crush injury th experiments have underlined the ætiological st Accepting that a gradual failure of glomerular f accompanies the diversions of renal blood flow that the filtered substances (innocuous in will tend to accumulate in the tubules and form ing and insuperable barrier to urine secretion cortical ischæmia has been overcome In the stages of the failure denervating the kidney by con anæsthesia could prevent this, and the accum material would then be continuously voided if an underlying and associated anoxæmia ha responsible—as in cases of incompatible trans measures directed towards reducing this an reduce mortality

We should recognise, I believe, that the " ischæmia " persists in anuria but can be overcome

LEGAL RESPONSIBILITY IN BLOOD-TRANSFUSION

James (Oct. 3) must surely have misunder
whole object of my letter (Sept. 26) and he
considerations which cannot be discussed
in correspondence columns

me I feel it is essential to point out that many
d disagree categorically with his statement
llergic manifestations of migraine are quite
se of other allergic conditions—asthma,
and nettlerash—in that migraine cannot
on allergic grounds and that skin tests are
ive. The histamine skin test is positive in a large percentage of cases of migraine and a number of us consider that it is treatable by desensitisation with neostigmine [1,2] as well as by other methods

This goes to support my contention that if asthma, hay fever and nettlerash are contra-indications to being a blood-donor then migraine should also be included. Whether the three former really are capable of being transmitted in the weak dilution which is probable in the pooled fluid is a matter about which Dr James knows far more than I do

GRADING OF S H M O s

SIR,—The statement concerning the review of senior hospital medical officers which you published last week (p 829) calls for one or two comments

(1) "The Ministry replied that the status of all the practitioners originally graded as S.H.M.O had been thoroughly reviewed on more than one occasion

This is categorically untrue. I cannot say how many are in my position but probably I am not unique in that my case has been reviewed once only Such cases must be well known to the Ministry's officials. Of course a review may have taken place without the victim having been appraised of it Perhaps this is what the Ministry means.

(2) The original grading of S.H.M O was made as a provisional status to cover those practitioners who were more than registrars but did not quite measure up to full consultant status. In 1949 it was clearly held out that good work would lead to promotion, and the grading of S H.M O would gradually cease. If subsequently it has been found convenient" not only to retain the grading S.H.M.O but to increase the numbers of practitioners so graded in such a way that soon S H M O.s will outnumber consultants in some specialties, then such a convenience should not be adopted at the expense of practitioners graded before the change in policy Surely these are entitled to a no-detriment clause As matters stand at present the Ministry can be fairly charged with a breach of faith

(3) What is probably more important than this injustice to individuals by the Ministry is the effect of the Ministry's statement on the development of the health service This statement will have the effect of fixing a "caste system—where the Ministry has been pleased to call you there you stay for life No allowance is made for original and useful work. It is no argument to say that the individual can change his job; the Ministry's officials know probably better than most that such advice is merely adding insult to injury for they themselves take care that, in some specialties at any rate an insufficient number of consultant posts is advertised. If it is now difficult to fill house posts because of the past and present policy regarding registrar status I submit that further freezing into a caste system will choke off most newcomers to the profession whose mistaken idea it is that they might contribute usefully to medicine by actually working A caste system which refuses to admit for consideration original work must inevitably mean that the most important thing in medicine is to get to know the right people on the right committees. As this can only be done in "centres" the least the Ministry's officials should do is to stop saying that the health service is improving conditions and standards at the periphery The reverse is now in process and what little good the health service has done to improve peripheral medicine will now be undone Is this the intention?

There is no real difficulty in the situation if the Ministry does in fact not wish to destroy an important part of the health service fabric All that is required is that without changing the establishment of a given post, an individual may on proving his worth be upgraded himself the post to revert should he leave it. If this minor modification is unacceptable to the Ministry as a principle of simple justice then the charge of bad faith, not only with S H.M O.s but with the whole profession of medicine, will be substantiated

S.H M O

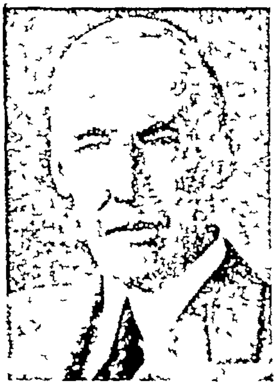
Obituary

EWEN JOHN MACLEAN

Kt., T D, M.D, LL D Edin, D.Sc Manc., LL D Wales, F.R.C.P, F.R.C.O.G, F.A.C.S, F.R.S.E, D.L

Sir Ewen Maclean, who died in Cardiff on Oct 13 at the age of 88, was the doyen of the profession in South Wales and of his specialty in the country generally Born of Highland parents, he was brought up in Carmarthen and attended the local grammar school, from which he proceeded to Edinburgh University He graduated as M.B with honours in 1889 and as M D, also with honours, in 1891 He later became M R C P and he was elected F R C P in 1922

After holding a resident appointment in the Bristol Women's and Children's Hospital, he went to the Chelsea Hospital for Women as a registrar and there started his life's work in obstetrics and gynæcology In 1901 he was appointed the first honorary gynæcologist to Cardiff Infirmary (later Cardiff Royal Infirmary) and he served with distinction in that office until he retired in 1931 with the rank of consulting obstetrician and gynæcologist On the creation of the Welsh National School of Medicine in the University of Wales in 1921, he was appointed professor of obstetrics and gynæcology, a post which he occupied for ten years From the time when he went to Cardiff he had been the pioneer of obstetrics and gynæcology in South Wales He built up a large private and hospital practice and impressed both academic and local authorities with the importance of this subject, especially in relation to maternal mortality and to maternity and child welfare



[Western Mail and Echo

As a clinician Sir Ewen was conscientious, thorough, and conservative, while his teaching was clear and to the point His ability to recall incidents in his vast clinical experience and to deduce general principles from these added to the weight of his instruction, while his long-headed sagacity in surveying the various aspects of a difficult case was illuminating It was, however, as an administrator and in council that his greatest gifts appeared, and this led to his being a member of innumerable committees and chairman or president of many of them He was for years a member of the council of the British Medical Association and was chairman of the representative body from 1910 to 1912—during the stormy days when Lloyd George's National Health Insurance Act was being hotly debated In 1928 when the annual meeting of the B M A. was held in Cardiff, he was elected president and later he became a vice-president His local work for the association included the presidency of the South Wales and Monmouthshire Branch, and the chairmanship of the Cardiff Division and of the contract practice subcommittee of the Welsh Committee He was one of the founders of the Royal College of Obstetricians and Gynæcologists, of which he was a foundation fellow For many years he served on the college council, and in 1935 he was elected president, an office which he occupied with his usual ability and distinction until 1938 In the early formative years of the college his wise counsel and far-seeing wisdom were of great value in the guidance of affairs, and he was largely responsible for laying the firm foundations from which the college has grown to its present position The honorary fellowship of the college was conferred on him in 1947 when the college received its Royal Charter When the National Health Service was introduced in 1948 he was appointed one of the original members of the board of governors of the United Cardiff Hospitals and he served in this capacity until shortly before his death

In the first world war Maclean was adjutant to the Third Western General Hospital in Cardiff with the rank of Major R A M C (T F), and in 1917–18 he the Eaton Hall Officers' Hospital, at Chester, rank of lieutenant-colonel, and later the Third General Hospital

Many honours were conferred upon him He wa of the peace for the City of Cardiff and a deputy of the County of Glamorgan In 1927 the American Surgeons gave him its honorary fellowship, whi he received the honorary degree of M D from the of Melbourne in the course of a world tour which on behalf of the British Medical Association. He the honorary doctorate of laws from Edinburgh U in 1933 and from the University of Wales in 19 University of Manchester made him an honorary 1940 He was knighted in 1923

“ Sir Ewen Maclean,” writes a friend, “wa the old school, but he was one of the best that school He witnessed the growth and dev of modern obstetrics and gynæcology and wa alive to the significance of each advance in Personally he was one of the most charming —kindly, urbane, and patient. His ethics and of social conduct were rigid and he looked for qualities in those with whom he worked A kn *delightful colleague, it was a pleasure to* work and those of us who will not again see his tal guished figure will for long mourn a staunch an outstanding public personality ”

Sir Ewen, who was a bachelor, was the brother of Sir Donald Maclean, at one time of the Board of Education

I WALKER HALL

M D Manc

Dr Walker Hall, emeritus professor of path the University of Bristol, died at his home at on Oct 9, at the age of 80

He qualified at Manchester in 1890 and three later took his M D In 1906 he left Manchester, he was lecturer in pathology, to go to Bristol as gist and bacteriologist to the Royal Infirmary, 1909 he became the first professor of pathology university He relinquished the chair in 1933 to the first director of the department of pre medicine at Bristol, and until his retirement in worked, in conjunction with Prof R H Parry, up the new department which included the la of public health, the public analyst, and pathology

Dr Walker Hall's work in the interests of health became known throughout the world D early part of the century he worked in close collab with Dr D. S Davies on the problem of the carrier , and, following in the footsteps of William he aided the medical profession in the problem of fever In 1916 he made valuable laboratory investi in connection with cases of bubonic plague in over four hundred rats were examined, and the flea, which is the common transmitter of the bacillus, was found His interest in the bacter control of pasteurised milk is shown by the his articles on the subject

He retired seventeen years ago, and began to for the Bar, but his studies had unfortunately discontinued owing to the illness of his wife.

R H P writes “ He was a most loyal chief, those who knew him in the early days of the pre medicine department thought very highly both personal attainments and of his administrative He was a great lecturer and teacher and a most ch companion ”

WILFRED JOHN PURDY

M.B Edin.

Dr Purdy, who died on Aug 28, was best kno his work on filterable fowl tumours, largely ca in collaboration with the late W E Gye He in 1882, in Derbyshire, the son of a lace manufa On leaving school at 15 he at first helped his and was later apprenticed to a lithographer with acquired skill in draughtsmanship which proved in later life After another period in the lace tr

dinburgh at the age of 27 to study medicine ecame attracted to pathology At Edinburgh ich influenced by a fellow student W E Gye D Bullock) who came from the same part of After two years of clinical medicine he was for military service in the first world war At the war an educational grant enabled him to in pathology under Shaw Dunn
ed the scientific staff of the Medical Research 1920 and worked with Gye on the poisonous of colloidal silica they published three papers Then after some work on measles yielding esults, Purdy joined in Gye s work on fowl In 1925 Gye and Barnard published their the aetiology of tumours in this Gye main at for transmission of fowl tumours with o factors were necessary a non-specific virus ecific factor derived from cells there were ications concerning the aetiology of cancer in Work supporting this theory was published in book, *The Cause of Cancer* by Gye and Purdy t 17 years until 1942 Purdy worked with st the theory largely by immunological tech d by himself he published several papers on the on of fowl tumours in ducks Purdy was to ry loyal colleague and not a little of a hero r His work was most meticulous and every xamined most critically His careful drawings s were a great asset in his published papers
Gye became director of the Imperial Cancer Fund Laboratories, Purdy, still a member of al Research Council staff, was seconded to him On his retirement in 1942 he went to linical pathology at Beverley in Yorkshire and 946 helped to build up a pathological depart he Margate and District General Hospital
rdy was of a retiring disposition and rarely meetings. He was helpful and friendly to all him; and even those who disagreed with his out cancer had a high regard for his qualities rived by his wife

JOHN HENRY BADCOCK
F R C.S. F.D.S

dcock was 80 years of age when he died at on Sept. 28 Inevitably most of his coevals leceased him but many of a younger genera n a position to appreciate his services to the ofession.
eived his professional education at the Royal d Charing Cross Hospitals, and obtained the ions of L.D.S in 1887 and M.R.C.S in 1890 In y a year after qualifying in medicine he was l an assistant dental surgeon at Guy's Hospital 895 he became dental surgeon In 1898 he had le lecturer in operative dental surgery and in n with this lectureship he introduced the subthodontics, in which throughout his professional ok the deepest interest.
4 to the great regret of both his colleagues lents, Badcock resigned from Guy s Hospital ewhat sudden step which there is reason to e afterwards regretted Nevertheless he found scope in connection with his profession apart al practice and he used it to the full He was associated with the affairs of the British Dental on of which he had been elected a member in d he served as its treasurer from 1910 to 1924 ident in 1925 His interest in orthodontics led to the foundation of the British Society for the Orthodontics of which he was the first president 931 he presided over the second International tic Congress. His work in dentistry was d by the Royal College of Surgeons when it im to the fellowship in 1932 and to the fellow he Faculty of Dental Surgery on its institution. other distinctions he became president of the gical section of the Royal Society of Medicine and examinerships and many other appointments o make his life an extremely busy one
ck was a notable teacher and was prodigal of hich either he or others brought to fruition s example was the well known Badcock screw—as familiar in orthodontics as the Spencer Wells forceps in general surgery A man of considerable intellectual powers he loved beautiful things and enjoyed outdoor pursuits such as walking, climbing and boating He had great charm was quiet and gentle in manner, and was kind and helpful to a degree His teaching and example influenced and will continue to influence, many who knew him

JOHN VINCENT FORREST
C.B., C.M G., M B Edin.

Colonel Forrest who died at his Belfast home on Oct 10 will be chiefly remembered in Ulster for his association with the Royal Victoria Hospital Belfast of which he was medical superintendent from 1920 till 1930 His success in this office owed much, however to his previous wide experience and distinguished career

Born in 1873 he was the son of the late Mr William Forrest a member of the Legislative Council of Antigua in the Leeward Islands. He studied medicine at Edinburgh University and after qualifying M.B in 1894 joined the Army Medical Services He served both in the South African war and in the first world war In the 1914–18 war he served first on the staff of the D D.M.S at Boulogne and in 1917 he was appointed D D.M.S to the Italian Expeditionary Force For his services he was appointed C M G in 1916, and C.B in 1919 and he was six times mentioned in despatches

It was with this solid achievement behind him that he started in 1920 his ten years work at the Royal Victoria Hospital, with all the problems presented by a continually expanding institution These were days when paper counted much less than personality and when administration by its very elasticity and lack of tabulated regulations made the character and judgment of those responsible vitally important His great experience and sound judgment, together with a quiet but persuasive way with his lay and medical colleagues, levelled out many an obstacle On his retirement in 1930 the management committee and staff paid a tribute to his services by a donation to the building fund of the new maternity hospital and nominated him as a life governor

Colonel Forrest is survived by his wife with a son and a daughter

Notes and News

CLINICAL RESEARCH AT THE MIDDLESEX

THE new Institute of Clinical Research, which was opened is week as a part of the Middlesex Hospital Medical School, ll provide a vantage point to which the clinician may with aw for a spell to consolidate and develop the ideas which ve sprung from his day to day work and which he has rhaps had to put aside for want of time or means to investi te them further The board of governors of the hospital ve decided to devote a considerable proportion of the spital's endowment fund to research, and, with the new stitute in mind, they bought a modern four storey building, nich had been used as a boys' club, a few minutes' walk from e hospital, so those who are fortunate enough to work in e agreeable surroundings that have now been prepared ere will be in fact detached, but not too remotely, from the isy hospital scene

The hospital's clinical research committee will allot grants om the income of the endowment fund to individual search-workers, who will then take their place in the institute r a prescribed term Each will be sponsored by one of the ddlesex consultants, who will supervise progress, but ose who receive grants need not necessarily be members of e hospital staff The equipment and laboratories of the stitute will be at their disposal, but any additional apparatus at they need will have to be paid for from their grant or om other grants that they may hold

The ground floor of the building is mainly taken up by six mfortable consulting rooms where patients, chosen for vestigation and follow up in a particular piece of research, ay be interviewed and examined These rooms include one rge one where a number of people can be dealt with at the me time, the plan is to use this room not only for patients it for students or other volunteers who are being used as sub ts for an experiment No great number of patients will be in e institute at any one time, so only a small (but handsomely rnished) waiting room has been provided On the first floor ere is a common room for informal gatherings of the staff d for occasional scientific meetings Then there are rooms different sizes for the research workers, so that each may ve a place to call his own The basic furnishings of these oms are simply a desk and a small laboratory bench, the cupant fills in the details

By no means all the doctors in the institute will deal rectly with patients, for clinical research is to be interpreted ry broadly as research by clinicians Some may need no ore than one of the smaller rooms on the first floor where ey can install their equipment and get straight to work on eir chosen problem Others will make many calls on the ochemical and pathological laboratories on the floor above tached to the biochemical laboratory is a measuring room using precision instruments The two laboratories will be the immediate charge of technicians from the corresponding partments of the hospital and they will keep in close touch th the parent laboratory A particularly useful feature of e third floor is the workroom where apparatus can be made modified to meet a special need, clearly, it is a much eaper proposition to adapt standard equipment to do the b in hand rather than call on the manufacturers to make a w instrument Demands on the workroom are expected be heavy On the top floor there is accommodation for boratory animals, with a roomy run for the dogs on the roof ray plant is installed in the basement in the ordinary way us will be used to examine those animals whose response to experiment can be judged radiologically, but a generous ansformer has been selected which can supply any kind of -ray tube that may be brought by someone doing research at is predominantly radiological

The institute, which is under the direction of Prof Alan ekwick, strikes out on a new and promising line For one ing it will give opportunities for a more deliberate and etter planned approach to clinical research, and, for another, will help to emphasise to newcomers the importance of ving a full explanation to the patients who have been vited to take part in a research inquiry

PREVENTION OF BARBITURATE POISONING

IN the *British Medical Journal* of June 13, 1953 (p 1335), r E Mackernan suggested that, to prevent deaths from verdose of a barbiturate drug each tablet should contain small amount of ipecacuanha which would act as an emetic when too many tablets were taken. British F Proprietaries (Middle Street, Taunton, Somerset) inform that they produce a range of standard barbiturates " safe in this manner" They say

> "Our experimental trials have shown that it is possible quantity of emetic in the form of the alkaloids of which has no significant pharmacological activity when quantities of tablets are used On the other hand, if an is taken an emetic dose is obtained before the barbiturate reaches lethal amounts. Moreover the action of emetic, which is due to direct gastric irritation, is prompt to ensure the elimination of the bulk of the barb before absorption occurs."

DANGEROUS DRUGS ACT

THE Home Office has issued an order[1] which part III of the Dangerous Drugs Act, 1951, to N morphine (the approved name is nalorphine) From Nov this drug will come within the provisions of the Act and regulations made thereunder

NEW MATERNITY BENEFITS

THE new maternity benefits,[2] introduced by the Nat Insurance Act, 1953, will be available to mothers babies are born on or after Monday, Oct 26 The new b are

Maternity grant of £9 for each baby born. This replaces present maternity grant of £4 and attendance allowance of £1 week for four weeks. The attendance allowance has been

Home confinement grant of £3 for mothers whose babies are at home or elsewhere than in a hospital or institution *tenance is paid for from public funds* This is an entirely new

Maternity allowance of £1 12*s* 6*d* for eighteen weeks fo in paid work and paying full national insurance during the year starting 15 months before the baby is born allowance (total £20 5*s*) replaces the present allowance of £1 for thirteen weeks (total £23 8*s*) paid at present to women paid work.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

THE President of this society for the session 1953-5 Dr F NORMAN WHITE, whose distinguished career began the Indian Medical Service and included a long period in Health Organisation of the League of Nations and in School of Hygiene in Athens In his presidential Oct 15 Dr White recalled some of his experiences of major epidemic diseases, of which the first was the p of influenza that attacked Europe in the spring and of 1918, and in the autumn swept through India, where of the monsoon had already caused hardship through shortages Nowhere in the world was the epidemic so as in India, and in two months it caused 6 million there Rural areas suffered more than towns, and the was especially severe on young people By November, the epidemic was over, but Dr White, who during this was doing the work of the sanitary commissioner of government of India, and upon whom lay most of responsibility for coping with the emergency, showed had been a tragedy the magnitude of which was not appreciated by those living outside India

He went on to recall the great outbreak of typhus relapsing fever which, in 1920, spread from Russia to P and the neighbouring countries and which came as a immediate threat to war-devastated Europe Dr had been invited to take charge of an international ep commission set up by the council of the League of Na and in the autumn of that year he left for Poland with then the director of the State Serum Institute in Copen and Pottevin, of the Office International d'Hygiène P Conditions were appalling, there was typhus in every sometimes in every house, and refugee trains brought victims, alive and dead Relapsing fever and cholera to the miseries of these disorganised countries, and the preventive measures were few and called for much labo organisation Dr White mentioned some of the great who directed the relief organisations—Nansen, Rajchman Poland, and Tarassevitch of Russia—and he paid trib the Russian doctors and nurses who worked at such de risk to themselves in apparently hopeless circum

In 1922 the League of Nations sent Dr White on a to the Far East, where he met a number of out personalities, such as Shiga and Yersin, the discoverer of plague bacillus This tour led him to suggest the cre an epidemiological intelligence bureau at Singapore, un direction of the League of Nations. The bureau was

Iniversity of London

At recent examinations the following were successful:

D.C.P.—J B. Adamson J D Arneaud M. C Berenbaum , R. Chapman, Siri Krishen Chopra Manoranjan Datta, B R avis, N U C Godfrey W F Hunter Samrit Jatinandana C. March Mary Ralston, W A Russell, M. P K. Shoobridge C. Squires H J Woodliff

D.P.H.—P P M Browne James Clearkin, K. A Rahman, T Subramaniam D R Thomson David Ungar

D.T.M. & H.—Paja Sirivorasarn

cottish Conjoint Board

At recent examinations for the diploma of licentiate of the oyal Colleges of Physicians and Surgeons of Edinburgh, and he Royal Faculty of Physicians and Surgeons of Glasgow he following were successful

J. A. Childs J C Douglas Ellis Hanford Santosh Khosla, J McA. Kirby G D B. Lindsay Patrick Murray Marie J ilbchester Mohammad Hasan Rizvi W J Ross, R. MacG Wight.

oyal College of Obstetricians and Gynæcologists

At the annual dinner of the college held in London n Oct. 16 the President Mr A. A. Gemmell referred to some f the college s plans. Next year was its silver jubilee and an ttractive programme in celebration was being arranged for he days July 13–15 when one of the functions would be ttended by Queen Elizabeth the Queen Mother The ollege museum continued to expand a steady flow of xhibits was coming in and it was clear that the potential xisted to create one of the best museums of obstetrics and ynæcology in the world The library must still concentrate n acquiring historical works until the college had more oomy premises To enable the college to enlarge its quarters, nuch more money was needed, and it had been decided to eopen the appeal fund next year with a new building as the bjective Sir Ronald Weeks would preside over the appeal Ir Gemmell was replying to the toast of The College pro osed by Sir Francis Walshe F.R.S Prof J F Cunningham elcomed the guests who as Mr Iain Macleod Minister of Health, observed in his reply considerably outnumbered the osts Mr Macleod hoped that Sir Ronald would let him now if there was any way in which he could help directly or ndirectly in the work of the college s appeal for funds. A istinguished visitor from the Commonwealth Sir Edmund Herring, lieutenant-governor of Victoria, also replied in riendly terms for the guests. He would he said like to ee more people from Great Britain making the journey o Commonwealth countries to see what the inhabitants were ike and how they lived; he felt sure that two-way traffic was one of the best ways of drawing together the Common wealth family

At a meeting of the council on Oct 16, with Mr Gemmell n the chair the following were admitted to membership:

L. J Abramowitz, Subrahmanyan Alankaram, W J R. Anderson . S Andrew, A K. Bose J C Brace T J Buckley, Samuel Burke . K. Burt, J G Cameron, R. S Casement, P W Christina Chow Maureen D Connolly, R. L. Edwards M B Flanagan F M C. oster Kathleen M. Frith, M C. G Grant, P B Guastalla, R. H J amlin, J. W S. Harris, J M Holmes, C A Jones, R. L Jones, R. Macdonald, Betty Mallace, G A Manly D N Menzies, M C. Hobelow J J Nattrass, H H Neifeld, F N Neser, J P. O Dwyer R. Patnaik, Clara Phillips, B G Pickles, William Rotheram S. Scott, J M. Stewart, R. A. Struthers, Valerie M. Thompson J Thornberry Harry Ulman C G Wilson.

oyal Sanitary Institute

At a meeting to be held in the town hall St Helens, at 0.30 A.M on Thursday Nov 5 Mr M Ward will read a aper on Sewerage Problems in Subsiding Areas and Dr G Brien and Mr D W Richardson will speak on Acquisition nd Modernisation of a Common Lodging House At 2 30 P.M n Wednesday Nov 11 Mr F T Wilkins, PH D will open discussion at the institute 90 Buckingham Palace Road ondon S.W 1 on Air Pollution and the London Fog of ecember 1952. An exhibition on smoke and smog will be pened on Monday Nov 9 in the museum of hygiene at the nstitute The exhibition will remain open until Dec 5

Royal College of Surgeons of England

On Oct 20 H.R.H the Duke of Edinburgh was admitted to honorary fellowship of the college

Mr Geoffrey Keynes will deliver the Cecil Joll lecture on Thursday Nov 12 at 5 P.M., at the college Lincoln s Inn Fields, London W C.2 He will speak on Investigations into Thymic Disease and Tumour Formation. Sir Reginald Watson-Jones will deliver the Bradshaw lecture on Wednesday Dec 9 at 4 P.M., at the college. His subject will be Fracture Treatment in the Next Half Century On Thursday Dec. 10 at 5 P.M Mr St. J D Buxton will deliver the Robert Jones lecture He will speak on Arthroplasty

Faculty of Anæsthetists—Dr Frankis T Evans will deliver the Frederic Hewitt lecture at the college, Lincoln's Inn Fields London, W C.2, on Friday Oct 30 at 4.30 P.M. He will speak on Freedoms of Anæsthesia.

Royal College of Physicians of London

On Oct 16 the Bisset Hawkins medal was presented to Dr W N Pickles, of Aysgarth. The citation ended as follows

> "As a student of epidemiology he stands in the forefront. But perhaps his outstanding achievement is the demonstration that scientific observation and deduction is not only possible under the pressure of a busy general practice but is a constant stimulus to the quality of the service that the general practitioner can give to his patients."

Renal Association

At a meeting of this association to be held on Wednesday Oct. 28 at the Ciba Foundation, 41 Portland Place London, W 1 at 4 30 P.M. Prof E. B Verney F.R.S Dr B E Miles, and Dr A. A. G Lewis will open a discussion on Emotion and Renal Function.

Bathing pool for Paralysed Patients

An anonymous gift of £5000 to provide a bathing pool at King Edward VII Hospital, Sheffield for the treatment of patients paralysed by poliomyelitis has been made to Sheffield Regional Hospital Board. Earlier this year it was decided that a new physiotherapy department would be provided, but that a pool would have to wait until there was more capital

Charing Cross Hospital Dinner

The annual dinner held in London on Oct. 10 was attended by well over 200 members of the staff and past and present students. Dr C M. Scott, proposing The Medical School spoke of its progress and of the happy atmosphere which always animated staff and students. Dr E. C Warner the dean, said that the school was again able to accept 1st M.B students and thus covered the whole course for medical degrees The facilities for clinical instruction had been extended by providing special demonstrations at the Queen Elizabeth Hospital for Children, by arranging for domiciliary midwifery and by enabling students to live and study for three weeks in the homes of general practitioners. He mentioned that in the past three years five former students had obtained the degree of master of surgery—a number greater than had been attained by any other school. Mr David Trevor proposed the health of Mr Norman Lake, the retiring senior surgeon, and of Dr H. W C. Vines, who is retiring from the chair of morbid anatomy Mr Lake he said had been connected with the school since he entered as a student in 1906 and had been senior surgeon for over twenty years—a period believed to be longer than that of any of his pre decessors; in addition to his distinction as a surgeon, he was a scientist of repute and an engineer of considerable skill. Professor Vines, as dean in the years following the late war had had the very responsible task of rebuilding the school, and he had been able to bring the departments of anatomy and physiology back to Charing Cross. Subsequently he had been chairman of the planning committee which had got as far as setting out detailed working plans of the new hospital and medical school Mr Lake and Professor Vines, in reply to the toast, made speeches which will long be remembered by those who were present. On behalf of the staff and students, Lord Inman, who presided made presentations to Mr Lake and Professor Vines. Of the funds collected the greater proportion will be used to establish a Norman Lake prize in final year surgery and a Prof H. W C Vines prize in pathology

---

In our advertisement columns this week application is invited for a post as junior assistant editor of *The Lancet*

Royal Society of Medicine

On Oct 16, Mr A. T Glenny, F R S, received the Jenner medal for his outstanding contribution to the prevention and control of epidemic diseases, notably diphtheria

Empire Rheumatism Council

Dr Otto Steinbrocker (New York) will be the guest lecturer in the council's weekend course to be held at the Arthur Stanley Institute, Peto Place, Marylebone Road, London, N W 1, on Nov 13 and 14

Reciprocal Social Security

A reciprocal agreement on social security between the United Kingdom and the Grand Duchy of Luxembourg was signed on Oct 13 The agreement will enable national insurance pensions and industrial injuries benefits to be paid in Luxembourg, while the corresponding benefits of the Luxembourg social insurance schemes will become payable in the United Kingdom Moreover, national insurance contributions paid in both countries will be taken into account for the purpose of benefits in either country The agreement, which is subject to ratification, is expected to come into operation next summer

British Medical Students' Association

This association is holding its annual general meeting Nov 5 to 7 in Bristol The annual ball will be held on Frid Nov 6 Further particulars may be had from D I. D Ho c/o M C R, Royal Infirmary, Bristol

Congrès International de Médicine Sportive

The tenth international congress of medicine as applied sport will be held in Belgrade on May 19–22, 1954 details may be obtained from the secretary general, Dr Smodlaka, Belgrade, Deligradska, 27, Yugoslavia.

Frenchay Hospital, Bristol

New operating-theatres and extensions to the department of neurological surgery at Frenchay Hospital opened by Sir Geoffrey Jefferson, F R.S, on Oct The two new theatres will more than double the operating capacity, and the neurosurgeons will be placed to deal with an emergency case which arrives long elective operation is in progress The theatres air conditioned and equipped with pressure steam sterili The department is the base for the neurological service of the South-western Hospital Region

Diary of the Week

OCT 25 TO 31

Monday, 26th

POSTGRADUATE MEDICAL SCHOOL OF LONDON, Ducane Road, W 12
4 P.M Dr C C Ungley Rôle of Vitamin B_{12} and other Hæmopoietic Factors in Megaloblastic Anæmias

OCIOMEDICAL ASPECTS OF DIABETES MELLITUS *

R E TUNBRIDGE
O B.E M.D M.Sc. Leeds, F.R C.P
PROFESSOR OF MEDICINE, UNIVERSITY OF LEEDS

DIABETES mellitus is one of the commonest medical orders In this country today there are about 150,000 own diabetics, and probably there are a similar number yet undetected. More than half of all diabetics are over age of 40 and the proportion of the population over is rapidly increasing; thus within twenty years this ntry is likely to have at least half a million diabetics nearly 1% of the population The treatment of betes mellitus therefore is a national as well as an dividual problem.

Diagnosis and Detection

Beaser (1948) analysed the early symptoms of all tients attending a diabetic clinic, and found that 34% d classical presenting symptoms, and altogether 77% mptoms suggestive of diabetes mellitus Diabetic mplications were a presenting feature in only 19%, d weight loss was noted initially in less than half the tients. Beaser remarks that the severity of diabetes ellitus measured by the patient's insulin requirement, influenced by the following factors, named in order importance: (1) a period of untreated glycosuria) metabolic decompensation, (3) age. A large proportion the adult patients were found to have had glycosuria r anything up to sixteen years before they came under eatment, and 80% had a history of glycosuria for at ast two years before receiving treatment. Simon (1953) a survey of diabetics living in the eastern health district Baltimore confirms this experience; for only 8% had d diabetes diagnosed early, compared with 78% in om it was diagnosed late

The so-called complications are the most important nical problems in diabetes mellitus, and their onset is lated to the duration of the disease Thus it is essential know whether adequate control of the diabetes fluences in any way the incidence of complications e Joslin school (1952) hold that poor control increases e liability to complications, but their results relate to e treatment of patients once the diagnosis has been ablished. Rabinowitch (1949) followed up for ten ars a series of private patients who had presented tially with glycosuria and some slight abnormality the glucose-tolerance test, such as an abnormal peak a lag type of curve, but who had had a normal fasting od-sugar and a normal blood-sugar two and a half urs after a meal. In all, 133 patients were studied; had been kept on diets as a precautionary measure, ile 49 had either not been dieted or else had soon carded dietary control and were therefore not included the dieted group The incidence of frank diabetes was ch higher in the group that had not been dieted Of series as a whole 39 (29 3%) developed frank diabetes incidence was higher in the patients with a family tory of diabetes mellitus This study for the first time vided evidence that precautionary dietary treatment the doubtful case lowered the risk of frank diabetes, it thus enhanced the importance of the detection ves in which the American Diabetic Association has aged for the last five years

The pioneer survey of Wilkerson and Krall in 1947 made at Oxford Mass. where of a population of 3 they examined the urine and blood of 3510—just r 70% of the inhabitants They used Benedict's test for the urine analysis, and capillary blood for the blood-sugar estimation They found 70 cases of diabetes mellitus 40 previously recognised and 30 new cases. The later surveys in Arizona (Joslin 1940) Brooklyn (Hartweg and Glenn 1951), Jacksonville (Ford 1949) Dayton (Sharkey et al 1950), St. Louis (McBryde 1949, Olmsted et al 1953), Gloucester, Mass (Getting et al. 1952) and in Canada (Kenny and Clute 1951, 1953) have all indicated that approximately one new case of frank diabetes is discovered for every one previously known

In the early survey at St Louis the urine samples were collected in bottles which were obtainable from pharmacists This method had obvious difficulties connected with preservation of specimens and collecting packing and sterilising of the containers A later suggestion that the pharmacist should test the sample of the urine was not acceptable to the public. For later surveys Drey (1950) worked out two new devices the Drey pack' and a simpler modification which should be of inestimable value not only in survey work but possibly also in the routine follow up of patients attending clinics In surveys true diabetes is commonly brought to light by the discovery of severe glycosuria Urine testing is especially valuable because of its simplicity but blood sugar estimation is more reliable if only a single test is to be used.

The Gloucester survey (Getting et al. 1952) illustrated the difficulties of detection surveys and especially the problem of human caprice.

> In this survey self testing sets were distributed after intensive propaganda and the instructions for testing were very simple 3232 persons registered for the sets, 1730 did the test, 1181 failed to test and 341 could not be traced. Of those testing, 75% reported no difficulty with the test, and 8% difficulty; and 17% could not follow the instructions Among those failing to do the test the cause was lack of interest in 40% and difficulty over the test in 29%. Further analysis of the age and academic standing of those who failed to test showed no significant difference from those who succeeded.
>
> Still more disappointing was the fact that of the 98 including 13 known diabetics, who obtained a suspicious response only 23 consulted their physician as requested if the result was suspicious.

The Gloucester survey underlines four features of any detection drive: (1) the difficulty of maintaining interest (2) the procrastination in doing tests (3) the inaccurate interpretation of tests, despite simple instructions; and (4) the failure of persons with a suspicious test to obey instructions and report to their physician. Getting et al suggest that testing should be done centrally and the patients followed up individually where blood-sugar analysis is necessary In volunteers it is impossible always to get specimens at a certain fixed time after a meal. Hartweg and Glenn (1951) have reassessed the data from some of the surveys and consider the following values are significant for capillary blood:

Hours after breakfast	*Blood sugar (mg per 100 ml.)*
½–1½	160
1½–2½	150
2½–3½	140
3½+	130

They suggest that these are minimal figures, and that where they are reached or exceeded it is advisable to do a full glucose tolerance test Other methods of detection use less elaborate techniques. Ford (1949) followed up the relatives of diabetic patients immediately after diagnosis and found 31 cases amongst 736 people tested. The Boston Health Department distributed testing containers to 2000 patients who were attending for mass radiography examination 1133 of the containers were returned in 16 instances there was glycosuria of the 16 patients 8 were known and 8 unknown diabetics

Diabetic detection surveys are costly in time, man power and material and must be repeated frequently

---

venth Banting memorial lecture of the British Diabetic Association, delivered at Leeds on July 17 1953

A further survey in Oxford, Mass, four years after the initial study, discovered new cases of diabetes mellitus not detected or suspected in the first survey (Joslin 1952)

All the surveys have nevertheless demonstrated frequency and importance of glycosuria Rabinowitch (1949) has also shown the importance of glycosuria as a herald of frank diabetes Whether detection drives, as recently organised in the United States, are the best method of discovering diabetes mellitus is still uncertain It is apparent that the profession needs to reorientate its views as to the significance of glycosuria, the need for blood sugar analysis, and the pitfalls in interpreting glucose tolerance findings, such as the danger of relying too much on fasting values and the importance of peak figures, lag curves, and the time of day when samples are taken

Treatment

The discovery of insulin revolutionised the attitude of both patients and doctors towards diabetes mellitus It is often said that nowadays patients die, not of, but with, diabetes mellitus Is this the whole truth? Despite more than thirty years' experience of insulin there remain many unsolved problems both as to its fundamental action and as to the best method of using it in individual cases

Rosenbuch (1945) asks "if the prognosis of diabetes in childhood—taking the long view—is, in spite of the progress of dietary and insulin treatment, more adverse than had originally been expected" Numerous reports (Dolger 1947, White and Waskow 1948, Root et al 1950, Larsson et al 1952) in recent years have emphasised the prevalence of the so called complications of diabetes mellitus—cardiovascular degeneration, hypertension, renal lesions, cataract, and retinal changes—and all have suggested that the onset of these is related to the duration of the disease Disagreement exists as to the part played by poor control in the causation of so-called complications, but there is general agreement that the most important factor is duration of the disease The evidence that cardiovascular and neuropathic complications are directly due to diabetes mellitus is not so sound as in the case of the more specific lesions—the aneurysmal dilatation of the vessels of the retina described by Ballantyne (Ballantyne and Loewenstein 1944, Ballantyne 1945) and the renal lesion described by Kimmelstiel and Wilson (1936)

I would emphasise that it is hardly justifiable to refer to the lesion described by Kimmelstiel and Wilson as a clinical syndrome The severity of the histological change seems to be related to the duration rather than to the severity of the diabetes, and although severe change is associated with albuminuria, hypertension, and retinitis, quite severe change is also found in diabetic patients who have died from non renal causes or accidentally. If these lesions are specific to diabetes mellitus, and proportional in severity to the duration of the diabetes mellitus, are they preventable? Are they less frequent in the well controlled diabetic? If so, what constitutes good control? And are the present methods and standards of treatment satisfactory?

WHAT IS GOOD CONTROL?

What constitutes good control? The greater freedom in therapy resulting from the introduction of insulin has tended to make physicians neglect earlier work and to be slow in applying physiological knowledge Allen and Sherrill said in 1922—and it is equally true today—"insulin has tremendously improved diabetic treatment but has not simplified it" Physiological and chemical evidence confirms the opinion of Allen (Allen and Sherrill 1922 Allen 1953) that dietary restriction, quite apart from its role in the prevention of obesity, is essential for good treatment. Houssay and Martinez (1947) found that in s which had undergone subtotal pancreatectomy the development of diabetes was accelerated by overfeedi Furthermore they showed that the composition of th diet within a fixed calorie intake had a variable eff A high-fat (lard) diet caused rapid development diabetes in all such rats, a high-carbohydrate d produced a similar but slower effect in all rats, when with a high protein diet only 75% of the rats becam diabetic Houssay and Martinez also compared th effects of giving the rats their food (*a*) in one meal a day and (*b*) divided into three meals Diabetes develop more rapidly in the animals fed once a day than in th fed three times a day Thus experimental work sugge that not only the total calorie intake but also composition of the diet is important

Kekwick (1952), treating obesity in diabetic and n non-diabetic patients, found that the composition of th diet as well as restriction of calories helped to determi the rate of weight loss

Stetten (1949) emphasised that in the diabetic anim the metabolism of carbohydrate, protein, and fat yiel compounds which can take part in the tricarboxylic ac cycle, so that interference with carbohydrate metabol may have repercussions on the metabolism of both p and fat Joslin's (1952) definition of diabetes mellit indicates clearly that the clinical syndrome of d mellitus has many possible ætiological factors, and th it is not always due to an absolute deficiency of insuli but may be due to a diminished effectiveness of ins secreted Considerable clinical, pathological, and expe mental evidence support his views Warren and LeComp (1952) found that in over a third of patients who h died with diabetes mellitus the pancreatic β cells and th islets of Langerhans appeared normal Wrenshall et a (1952) estimated at necropsy the insulin content of th pancreas in diabetic and non diabetic subjects and fou a lower average extractable insulin content in diabe subjects, in these the amount of extractable insu increased continuously with age from very low values i the young to approximately half normal values in the fifth decade That diabetes mellitus in man is not sim a matter of insulin deficiency is shown by compar of the insulin requirements of diabetic patients with th of patients who have had a total pancreatectomy f carcinoma of the pancreas The latter patients reta normal insulin sensitivity, and on liberal diets requ less than 50 units of insulin per day (Warren 1951)

Bornstein (1950a and b) and Willebrande et al (19 have recently described techniques for measuring th insulin content of blood, and have found considera reduction and variation in the blood insulin values patients with diabetes mellitus Even more striking is th report that the blood insulin values of patients with a initial level are rapidly restored to normal by treatme and that injected insulin does not per se increase the bloo insulin levels (Beaser 1952, Groen et al 1952) The findings, if confirmed, would suggest that once diabe mellitus is diagnosed vigorous treatment should be star immediately to restore the blood insulin values to norm in other words, insulin therapy should be begun at on even if this may not be required permanently

Soskin and Levine (1937) demonstrated that the r of sugar utilisation by the extrahepatic tissues var directly with the level of the blood sugar This confir the hypothesis of some clinicians that hyperglyc was not necessarily harmful, and that slow stabilisat first by diet and later, if necessary, by insulin, wit undue emphasis on normoglycæmia, was a sound met of treatment The experimental work of Dohan a Lukens (1947 1948), who produced persistent diab in cats by intraperitoneal injections of a glucose solut suggests that hyperglycæmia per se may be harm Many factors are concerned, however, in the regulati the blood sugar level, and alterations in this level not the only metabolic disturbances in diabetes

Reports on dietary control reveal striking differences in ractice (Lichtenstein 1944–45, Guest 1947, Tolstoi 1948, ilson et al. 1952). Mosenthal (1948) has divided the rotagonists into three groups—the purists, the middle f the-roaders, and the free-dieters. Beaser (1951), in n attempt to survey present methods of treatment, sent questionnaire to one in three of the medical members f the American Diabetic Association. 70% stated that ey aimed at normoglycæmia, and half of these physi ians also tried to obtain a sugar-free fasting urine. A rther 23% aimed at aglycosuria, and only 7% were not orried about glycosuria. All the physicians agreed that well-controlled diabetic should maintain an ideal eight and avoid obesity; that the diabetic should feel ell and fit, and should avoid both ketosis and hypo lycæmia. An analysis of the methods used to calculate he diets showed that the majority used a household erving technique, and that only 25% estimated the daily alorie needs by a formula. Beaser was in fact impressed y the similarity of the methods of treatment.

These findings go far to explain the fallacy of so many onclusions based on supposed dietary control. In eading published reports it is abundantly clear that one f the important factors in all therapy is the personality f the physician and the zeal with which treatment is dvocated by him and is followed by the patient. The rguments for and against the free diet are confused by eglect of these facts.

Forsyth et al. (1951) showed that of 50 patients on an nrestricted diet who were followed up for five years, 1 had to be put on to a controlled diet—in 2 cases ecause of the development of obesity, in 2 because of he development of hypoglycæmic reactions, and in 7 ecause of increased insulin requirements. In this short eriod of observation they found no proof that the develop ent of complications was related to the form of diet. ten-year follow-up from the Lichtenstein Clinic (Larsson t al. 1952) does not show any clear evidence in favour f the free, as opposed to the controlled diet. On the ther hand, the Joslin school (Joslin 1952) repeatedly tate that the incidence of complications is much lower n the well-controlled diabetic.

SURVEY AT LEEDS

With a view to analysing the ability of patients to aintain dietary control I undertook in the spring of 948 a survey of patients attending the Diabetic Clinic t the General Infirmary, Leeds. From a nominal roll of ll the patients living in Leeds and attending the clinic very fifth name was taken, making 103 in all. The atients were asked to keep a careful record of all meals or one week; and it was clearly explained to all taking art that the information was confidential. A social orker visited the home, first immediately before the urvey began, to assess home conditions and the economic osition, secondly during the week of the survey to check he record, and finally at the end of the survey to collect he results. In addition the patients kept an account f the money spent on food and in many cases gave full etails of family income. At the same time the cost of a iabetic diet was determined in four typical districts of eeds—the City Market, a new housing estate, a suburban rea, and one of the poorest parts of the city. The cost f an average diet corresponding to 14 Lawrence Black ines and 8 Red Lines was estimated both for the foods s purchased over the counter and also for the foods as n experienced caterer with good facilities for storage night purchase them. Of the 103 patients on the nominal oll 94 coöperated. The diets were analysed for food ontent, caloric value, correctness, and cost by Miss A. M. oyle, senior dietitian to the hospital, Dr. R. G. Paley, nd myself. Certain queries about household measures ere checked wherever possible, and where no such heck was possible the results were classified as unsatisfactory. It was found that the accuracy of the dietary treatment of the 94 patients was satisfactory in 16, moderately satisfactory in 44, and hopeless in 34. In the satisfactory group the variation in the calorie content from day to day was less than 15%, and in many cases it was of the order of only 5%. These results, I suggest, are probably no better or worse than those that would be obtained from many of the major clinics in this country or America, and they illustrate how liable to error are conclusions based on outpatient dietary control. It is very easy to maintain good dietary control for short periods in hospital, but it does not follow that a high percentage of those so easily controlled in hospital can maintain a satisfactory diet in their own homes.

Causes of Failure

Why do patients fail to maintain a satisfactory level of control? I suggest that this failure is due to three main groups of causes—psychological, social, and educational.

PSYCHOLOGICAL CAUSES

The psychological factor is especially prominent in the juvenile diabetic. In the pre-insulin days the problem seemed discouraging because the prognosis was so hopeless. Today, however, the position is different, and most clinicians will have experienced difficulty in stabilising the juvenile diabetic. Their reactions seem surprisingly different from those of children with other chronic diseases. The trauma caused by the discovery of diabetes appears to be deeper and more disturbing than the anxiety induced by other chronic diseases (Benedek 1948). It has been suggested that the disease is more prevalent in certain constitutional types (Daniels 1939); but Bruch (1949) in a report based on a study of 37 children showed that there was no uniform picture which characterised diabetics, in contrast to obese patients who showed a definite constitutional pattern. Herskovitz (1930) has, however, shown that in diabetes depression and hypochondriacal trends appear early, and an initial period of adjustment is necessary before making a psychological assessment. The psychiatric difficulties are much greater in the dependent type of individual, but the main problem is one of family adjustment, and psycho-analytical techniques are of little value. It is most important to evaluate the stability of the home, the marital relationships, the attitude to other children, and the special attitude of the child in relation to therapy. Unfortunately tolerance and understanding on the part of parents in the first few years is uncommon. Rather their attitude is one of self-pity ("What have I done to deserve this?"), rejection, or aggression combined with a perfectionist attitude ("I will not stand for it; if anything goes wrong it is not my fault"). The importance of these emotional conflicts is very clearly brought out by the work of Hinkle (Hinkle et al. 1951, Hinkle and Wolf 1952). He and his co-workers have shown that a stressful situation produces a fall in blood-sugar and the serum inorganic phosphate and a rise in ketonæmia, the effects being more distinct in the diabetic than the non-diabetic. They also recorded different responses in the postabsorptive state and following the injection of glucose. Situations leading to reactions of dejection, resentment, and loneliness were associated with higher and prolonged glucose-tolerance curves, whereas situations fraught with anxiety and tension might lead to a less elevated curve and were sometimes associated with relative hypoglycæmia in the third to fourth hour. These experimental studies have been applied both to the unstable, brittle diabetic and the elderly and relatively stable diabetic. Rosen and Lidz (1949) observed that in labile diabetics stressful situations were commonly associated with an exacerbation of the diabetes along with ketosis and coma. Likewise periods of relative security were associated with remissions, marked by reduced insulin requirements and a tendency to hypoglycæmia Over eating was shown to be a characteristic response to stress These findings help to explain the extreme instability of some juvenile diabetics Psychiatrists contend that insistence on a controlled diet is a very important factor in producing these situations, the child resenting both discipline—often aggressively imposed by the parent—and the fact that he is different from other children In consequence Mirsky (1948) and Benjamin (1947) have suggested that juvenile diabetics should be placed on a free diet It is interesting to compare this view with the findings of Forsyth et al (1951), who showed that a free diet failed to control adequately their juvenile and young diabetic patients but seemed more satisfactory with the older group What has been said about the juveniles applies equally to all diabetic patients The older patients, however, have learnt some degree of restraint, particularly of their emotions Even though they do not necessarily react so openly, their reaction may still be similar to that of younger patients, and the experimental work of Hinkle et al (1950) confirms this I think most would agree with Rosen and Lidz (1949) that with few disorders is it more clearly necessary for the physician to consider the patient's problems and idiosyncrasies Undoubtedly the erratic course of a number of diabetics is partly due to the patient's failure to adjust to the new situation, and partly to the physician's failure to realise the importance of this mental factor

SOCIAL CAUSES

The social impact of diabetes mellitus is equally neglected In the past diets were often prescribed in which four meals consisting of breakfast, lunch, dinner, and a supper snack were prescribed, without any recognition that few working class families had, even before the late war, two cooked meals a day Furthermore, often the foods prescribed were unfamiliar to the patients or beyond the range of their pocket The cost of a diabetic diet has, until recently, been overlooked.

In the survey that I undertook in 1948 (Tunbridge 1949) it was shown that the cost of a diabetic diet averaged about 23*s* per week (ranging from 15*s* 6*d* to 40*s*) in the group who were considered to have kept strictly to their diet The lowest figure (15*s* 6*d*) was the only one under a pound and was from a Scottish housewife with a big family and a very large kitchen-garden The average cost of 23*s* corresponded very closely to the figure of 21*s* 6*d* calculated as the proper cost by a dietitian and myself By comparison the cost of food for non-diabetic members of the families ranged from 8*s* to 16*s*, with an average of just over 10*s* Each year a similar costing has been made for the same standard diet, and the figure for the spring of this year was 34*s* The failure of many diabetics, particularly the elderly, to maintain a steady diet is undoubtedly due to financial stringency The influence of cost on the diet was also shown in the detailed analyses Usually on the first two or three days after pay day the diets were reasonably accurate, but from then on when funds did not permit the buying of extras the diet rapidly deteriorated to one of bread-and-butter and tea Other important social considerations were the lack of various utensils and of suitable accommodation for storing food A further important dietetic finding was protein deficiency in the lower income groups, this was usual unless the patient had been persuaded to take a pint of milk a day The very sound rationing policy of the Government during the war years, with the special rations for diabetics, undoubtedly enabled many diabetics to maintain a reasonably adequate diet For many patients the lessening of restrictions will no doubt complicate dietary care and control Since there is still no cure for diabetes mellitus, [illegible] patient's life has to be replanned.

EDUCATIONAL CAUSES

Practice often falls far short of theory, and there a few accounts, other than in handbooks, to indicate th methods of educating diabetics It is often forgotten th even a medical man, with a physiological training bef the onset of the disease, requires at least three months dietary control before he can enter a restaurant an order an accurate meal without undue emotional tensio If this is the minimum time required for the educationa and emotional adjustment of a trained subject, and on of good intelligence, how much more difficult it mu be for the ordinary patient Another important difficult in the elderly is that they are extremely loth to chang their habits It is comparatively easy to instruct a youn adult, but much more difficult to make a lady of change her way of life She has always done thing own way, and in any case food is one of the cen features of her life

In this country we are deeply indebted to Dr Lawren for his admirable books and for his work in coöperatio with Prof R A McCance, F R S, and Miss E Widdowson, D SC, in analysing common foods in ter of available rather than total carbohydrate content Many instructional books, mostly American, are no available, these are designed to suit all tastes, includin that for strip cartoons

It is only the exceptional patient who can ap the full significance of the carbohydrate, fat, and content of a diet If one can make the patient un the carbohydrate equivalents and the significance total calorie intake, reasonable dietary control can achieved To attain and maintain such a standard necessary to use every device possible—talks, discu displays, demonstrations, and films—with the cons repetition of essentials The physician must tak active part in such teaching He needs of cours assistance of trained staff—e g, dietitians, almoners, specially trained nurses—but they should all form team and take every opportunity to help the diabetic his problems The patient is far more likely to coöpe if the physician takes a personal interest in his diet makes a point of asking detailed questions relating dietary control as well as showing readiness to questions in detail

Should patients weigh all their food? Routinel more practicable to use household measures than s and reasonable accuracy can be attained with former Ideally a patient should, from time to check her diet by weighing the food It is regrett that adjustable scales, which are much in demand, not obtainable at a reasonable price in this count though such equipment is readily available in the Uni States

Environment

CAMPS

The institution of diabetic camps has proved helpful in the treatment of the juvenile diabetic first camp for diabetic children was started by Dr L Wendt, of Detroit, in 1925 In North America in 1951 were eighteen camps that could take altogether children per annum, but only 1300 attended. Last the first time the British Diabetic Association decided organise such camps What is their object? Are be adjuncts to hospitals—in other words, conv homes—or are they to be holiday camps? I would with Marble (1952) that the primary aim of the should be to show diabetic children that they can part in the activities of a normal child, and that, reasonable attention to diet and regularity of meals insulin injections, they can live as ordinary children camp should be for diabetic children only, and und warden who is non diabetic and non-medical It is, ever, an advantage if a few of the staff are ecause it is good for the children to see adults whom ey know to be diabetic behaving in the same way as lults who are not diabetic The provision of holiday omes suited to the needs of older age-groups would be great value

HOSTELS

The difficulty of controlling satisfactorily the juvenile abetic is especially great when a child comes from a ome that is poor economically or still more important, notionally and morally To those interested in child elfare such children become a serious problem spending eir lives in and out of hospital, and obtaining little or schooling they are liable to become unemployable a very early age Several hostels for diabetic children ve now been opened in Great Britain; and we have ason to be grateful to Dr P Henderson, of the Ministry Education for the prominent part he has played in awing attention to the problem It is too early to sess the place and function of these hostels, but the perience gained will be invaluable

EMPLOYMENT

Employment is a difficult problem Diabetic patients e entitled to register as disabled persons yet most ysicians try to treat them as, and encourage them to lieve that they are, normal persons Certainly the jority of diabetic patients wish to keep to themselves knowledge of the disease; they hate being considered ferent. The increasing number of persons employed in vernment service, whether local or national has ated a new situation for the diabetic because all rsons in Government employ must be superannuable abetics find no difficulty in obtaining temporary ployment, but there is reluctance to take a diabetic tient on to the permanent staff of a Government partment. Certain types of employment create special blems—namely those involving extremes of physical ertion or long or variable hours of work, and those rying special responsibility involving the lives of hers. One of my patients, a platelayer, is extremely ll stabilised for five days of the week but, despite ive gardening over the weekend, finds it difficult to trol his diabetes on Saturdays and Sundays The blem of the person who works long hours and has no ess to a canteen also requires ingenuity in manage nt, since the usual diet does not permit of a very ral sandwich meal. It is difficult to obtain satisfactory trol for a patient employed in this kind of work ess he is highly coöperative and imaginative

ork which involves great public responsibility, ticularly for the lives of others such as that of pilot h a commercial airline, engine-driver or driver of lic road transport, is not suitable for diabetics, and refore should not be undertaken. The slightest error judgment due to variation in the blood sugar level, ht have such serious consequences.

he question of employment involving driving is ch more difficult Some licensing authorities have n reluctant to grant driving licences to diabetic ients.

ne of my patients, a married man with a large family o has been employed on road haulage for many years was ntly ordered by the Road Haulage Executive to give up -distance driving and take a depot appointment. He had diabetes mellitus for fifteen years and had no blemish on driving record As the change of employment was likely involve a loss of £3 a week in wages, I appealed on his alf; and the transport authorities have permitted him to tinue long-distance driving

requirements for acceptance of a diabetic as a driver, ides motoring proficiency should be known conscien usness in adhering to his régime and good control on oderate dose of insulin. Where there is an indication t the patient cannot be relied on to manage his diabetes, or there has been an accident which might be due to mismanagement of this disorder, the licence should be withdrawn. Human nature being what it is, only the most stringent care by diabetics will ensure public confidence in their normality But misbehaviour by the undisciplined patient should not mar the opportunities of the good diabetic.

Further Considerations

URINE TESTING

Diabetic patients with few exceptions should be able to test their urine The recent development of testing equipment such as the 'Clinitest' and 'Glucotest' has made testing simpler and easier Physicians tend to over-emphasise minute differences of colour even though they know that the finer distinctions may be of doubtful significance A test need only record absence a faint trace or a large amount of sugar The practice of asking patients to make readings in percentages is unwise since it gives them a false sense of accuracy If they are taught to test the urine, how often should tests be made? The answer of course is an individual matter for the physician and patient. There are some obsessional patients who will test innumerable times a day and there is little that can be done about it save to reassure them. The intelligent coöperative diabetic patient should be taught to test daily at least the second morning specimen passed after rising and before breakfast and at all other times when he feels it to be necessary With those who will not do this one must insist that they test a similar morning specimen of urine at least on three or four days every fortnight, and daily when they feel ill The testing of twenty four hour specimens of urine is a valuable means of assessing carbohydrate loss, but it is a hospital research investigation rather than one suitable for the routine surveillance of diabetics living at home. There is considerable divergence of opinion as to the wisdom of instructing patients in testing urine for ketone bodies, owing to the potential fallacies of routine tests. If the new commercial testing sets prove reliable both as to testing and keeping properties, the tests for ketone bodies could be taught to many more patients.

INSULIN THERAPY

Wherever possible, patients should be taught to administer their own insulin. Repeated demonstrations of the technique should be given, with ample opportunity for discussion Patients should bring their syringe and equipment with them to the clinic from time to time for routine overhaul Many difficulties would be solved by the adoption immediately of a standard syringe and the abolition within, say six months of all other varieties supplied to N H S patients

MARRIAGE

The mechanism of inheritance of diabetes mellitus is still not clearly understood, but it is generally accepted that a diabetic tendency can be inherited. Pincus and White (1933 1934) originally suggested that this tendency was inherited as a mendelian recessive but this view has not been accepted without reservation by later workers (Harris 1949 Watson and Thompson 1950) Certainly in juvenile diabetics there is considerable evidence for the hypothesis of Pincus and White, but one of the many difficulties in assessing diabetic inheritance is the variety of clinical syndromes which are labelled as diabetes mellitus and the possibility that clinical diabetes in the middle-aged is not the same disease as diabetes in the young From the point of view of inheritance however, it would seem unwise for a diabetic woman married to a diabetic man to have a family Far more important to the diabetic woman is the increased risk of toxæmia of pregnancy and of fœtal abnormality and mortality In recent years owing remissions, marked by reduced insulin requirements and a tendency to hypoglycæmia Over eating was shown to be a characteristic response to stress These findings help to explain the extreme instability of some juvenile diabetics Psychiatrists contend that insistence on a controlled diet is a very important factor in producing these situations, the child resenting both discipline—often aggressively imposed by the parent—and the fact that he is different from other children In consequence Mirsky (1948) and Benjamin (1947) have suggested that juvenile diabetics should be placed on a free diet It is interesting to compare this view with the findings of Forsyth et al (1951), who showed that a free diet failed to control adequately their juvenile and young diabetic patients but seemed more satisfactory with the older group What has been said about the juveniles applies equally to all diabetic patients The older patients, however, have learnt some degree of restraint, particularly of their emotions Even though they do not necessarily react so openly, their reaction may still be similar to that of younger patients, and the experimental work of Hinkle et al (1950) confirms this I think most would agree with Rosen and Lidz (1949) that with few disorders is it more clearly necessary for the physician to consider the patient's problems and idiosyncrasies Undoubtedly the erratic course of a number of diabetics is partly due to the patient's failure to adjust to the new situation, and partly to the physician's failure to realise the importance of this mental factor

SOCIAL CAUSES

The social impact of diabetes mellitus is equally eglected In the past diets were often prescribed in which four meals consisting of breakfast, lunch, dinner, and a supper snack were prescribed, without any recognition that few working class families had, even before the late war, two cooked meals a day Furthermore, often the foods prescribed were unfamiliar to the patients or beyond the range of their pocket The cost of a diabetic diet has, until recently, been overlooked

I would agr with Marble (1952) that the primary aim of the cam should be to show diabetic children that they can tak part in the activities of a normal child, and that, wi reasonable attention to diet and regularity of meals a insulin injections, they can live as ordinary children camp should be for diabetic children only, and under a warden who is non diabetic and non-medical It is, however, an advantage if a few of the staff are diab cause it is good for the children to see adults whom ey know to be diabetic behaving in the same way as lults who are not diabetic The provision of holiday mes suited to the needs of older age groups would be great value

HOSTELS

The difficulty of controlling satisfactorily the juvenile abetic is especially great when a child comes from a me that is poor economically or still more important notionally and morally To those interested in child elfare such children become a serious problem, spending eir lives in and out of hospital and obtaining little or schooling, they are liable to become unemployable a very early age. Several hostels for diabetic children ive now been opened in Great Britain; and we have ason to be grateful to Dr P Henderson of the Ministry Education, for the prominent part he has played in awing attention to the problem It is too early to sess the place and function of these hostels, but the perience gained will be invaluable

EMPLOYMENT

Employment is a difficult problem Diabetic patients e entitled to register as disabled persons, yet most ysicians try to treat them as, and encourage them to lieve that they are normal persons Certainly the ajority of diabetic patients wish to keep to themselves l knowledge of the disease they hate being considered fferent. The increasing number of persons employed in overnment service whether local or national, has eated a new situation for the diabetic because all rsons in Government employ must be superannuable. iabetics find no difficulty in obtaining temporary nployment but there is reluctance to take a diabetic tient on to the permanent staff of a Government partment. Certain types of employment create special oblems—namely those involving extremes of physical ertion or long or variable hours of work and those rrying special responsibility involving the lives of hers. One of my patients a platelayer, is extremely ll stabilised for five days of the week but, despite tive gardening over the weekend, finds it difficult to ntrol his diabetes on Saturdays and Sundays. The oblem of the person who works long hours and has no cess to a canteen also requires ingenuity in manage ent, since the usual diet does not permit of a very eral sandwich meal It is difficult to obtain satisfactory ntrol for a patient employed in this kind of work less he is highly coöperative and imaginative.

Work which involves great public responsibility rticularly for the lives of others such as that of pilot th a commercial airline, engine-driver or driver of blic road transport, is not suitable for diabetics and erefore should not be undertaken The slightest error judgment, due to variation in the blood sugar level ght have such serious consequences.

The question of employment involving driving is ch more difficult Some licensing authorities have en reluctant to grant driving licences to diabetic tients.

One of my patients, a married man with a large family o has been employed on road haulage for many years was ently ordered by the Road Haulage Executive to give up g-distance driving and take a depot appointment He had d diabetes mellitus for fifteen years and had no blemish on driving record. As the change of employment was likely involve a loss of £3 a week in wages, I appealed on his half; and the transport authorities have permitted him to ntinue long-distance driving

he requirements for acceptance of a diabetic as a driver sides motoring proficiency should be known conscientiousness in adhering to his régime and good control on moderate dose of insulin Where there is an indication at the patient cannot be relied on to manage his diabetes, or there has been an accident which might be due to mismanagement of this disorder, the licence should be withdrawn. Human nature being what it is only the most stringent care by diabetics will ensure public confidence in their normality But misbehaviour by the undisciplined patient should not mar the opportunities of the good diabetic.

Further Considerations

URINE TESTING

Diabetic patients with few exceptions should be able to test their urine. The recent development of testing equipment such as the 'Clinitest' and 'Glucotest' has made testing simpler and easier Physicians tend to over-emphasise minute differences of colour even though they know that the finer distinctions may be of doubtful significance A test need only record absence a faint trace or a large amount of sugar The practice of asking patients to make readings in percentages is unwise, since it gives them a false sense of accuracy If they are taught to test the urine, how often should tests be made? The answer of course is an individual matter for the physician and patient. There are some obsessional patients who will test innumerable times a day and there is little that can be done about it save to reassure them. The intelligent coöperative diabetic patient should be taught to test daily at least the second morning specimen passed after rising and before breakfast, and at all other times when he feels it to be necessary With those who will not do this one must insist that they test a similar morning specimen of urine at least on three or four days every fortnight and daily when they feel ill. The testing of twenty four hour specimens of urine is a valuable means of assessing carbohydrate loss, but it is a hospital research investigation rather than one suitable for the routine surveillance of diabetics living at home. There is considerable divergence of opinion as to the wisdom of instructing patients in testing urine for ketone bodies owing to the potential fallacies of routine tests If the new commercial testing sets prove reliable both as to testing and keeping properties, the tests for ketone bodies could be taught to many more patients

INSULIN THERAPY

Wherever possible patients should be taught to administer their own insulin Repeated demonstrations of the technique should be given with ample opportunity for discussion Patients should bring their syringe and equipment with them to the clinic from time to time for routine overhaul. Many difficulties would be solved by the adoption immediately of a standard syringe and the abolition within, say, six months of all other varieties supplied to N H S patients

MARRIAGE

The mechanism of inheritance of diabetes mellitus is still not clearly understood but it is generally accepted that a diabetic tendency can be inherited. Pincus and White (1933 1934) originally suggested that this tendency was inherited as a mendelian recessive but this view has not been accepted without reservation by later workers (Harris 1949 Watson and Thompson 1950) Certainly in juvenile diabetics there is considerable evidence for the hypothesis of Pincus and White but one of the many difficulties in assessing diabetic inheritance is the variety of clinical syndromes which are labelled as diabetes mellitus and the possibility that clinical diabetes in the middle-aged is not the same disease as diabetes in the young From the point of view of inheritance, however, it would seem unwise for a diabetic woman married to a diabetic man to have a family Far more important to the diabetic woman is the increased risk of toxæmia of pregnancy and of fœtal abnormality and mortality In recent years owing to the coöperation of obstetricians with physicians, the outlook has improved, but the most important factors, in my opinion, in deciding about marriage are personal ones A stable partnership, a settled home life, and the added purpose to life given by children give such emotional satisfaction that control of the diabetes is likely to be better It is wrong to suggest that a diabetic should not marry and that the diabetic woman should not have a family The facts of the position should be carefully explained and decisions left to the individual

INSURANCE

For many years it has been suggested to diabetic patients that their expectancy of life, if they maintain good control, does not fall far short of that of a normal individual Joslin was the first to preach this gospel, and in his enthusiasm went so far as to suggest that with the greater care diabetics exercised over their health their expectancy of life might be greater than normal Diabetic patients, however, were somewhat disconcerted by the attitude of the insurance companies, for, until 1940, these refused to consider a diabetic patient even at an enhanced premium In 1940 the Manufacturers Life Insurance Company of Canada first undertook life assurance for the diabetic A number of other companies have since adopted a similar policy, and in this country a diabetic can obtain insurance at an increased premium Blotner and Marble (1951), in discussing life assurance, laid down a number of points which they consider should decide the acceptability of a candidate—the age at onset of diabetes, the duration of diabetes, the prescribed diet and adherence to it, the insulin dosage and faithfulness in keeping to this, the frequency of urine tests for sugar and nature of the results, the common level of the blood-sugar, the incidence of coma and severe hypoglycæmic reactions, evidence of degenerative complications, chest radiographs and electrocardiographs, and how often the applicant attends his physician This list is formidable, and it would be interesting to know the relative importance attached by the insurance companies to each of these criteria Montgomery (1952), writing on his experiences with the insurance of diabetics, does not list so many factors but emphasises the importance of the conscientiousness with which the patient supervises his treatment and the regularity with which he attends his physician It is noteworthy that, although experience is limited, the insurance companies have so far shown no regret at having undertaken the insurance of diabetics In this country it is necessary for the diabetic to submit, in addition to the ordinary proposal form, a special diabetic questionnaire, and to give the name of the clinic he is attending and also that of his private doctor The diabetic questionnaire asks routine questions about diet, insulin, and duration of disease, but too much detail is not sought about blood sugar estimations and other points, although in the medical report all this essential information is required No specific question is asked about family history, and as far as I can judge the companies as yet attach no particular importance to family history in accepting or rejecting an applicant Similarly in this country radiographic examination of the chest is not demanded as a routine It is still early for a full actuarial assessment, but the fact that the insurance companies are not dissatisfied with their experience hitherto is reassuring for the diabetic patient, and also encouraging to those concerned in the supervision of patients

ASSOCIATIONS

This country, under the persuasive influence of Dr R D Lawrence was the first to form a diabetic association At first the project was much criticised, but the [illegible]e of such an association has been proved by the [illegible]r of similar associations founded in other countries, [illegible]nly for diabetics but also for patients with other chronic or crippling disorders Through the association members can keep up to date with current practice and thought, exchange ideas, and receive encourag without the need to declare publicly that they are su to the inconvenience of a diabetic life Success have their value in serving as a stimulus and encour ment to weaker brethren An association has also a in educating the public as well as the patient and medical profession, and it can make representations official bodies about matters, such as emplo driving licences, syringe manufacture, rationing, or foods, and insurance, which are so important to individual patient

RESPONSIBILITY FOR TREATMENT

It is estimated that in Great Britain today the 3 proved cases of diabetes mellitus per 1000 o population Joslin considers that for every k diabetic an undiagnosed case of diabetes exists, so one could assume that on the average in this countr general practitioner might be expected to have at l a dozen diabetic patients on his list at any one With this limited clinical material and the lack necessary facilities for blood sugar determination, practitioner cannot be expected to assume the responsibility for surveillance, although he should versed in the diagnostic problems and the princi routine management It is essential for the patient to visit periodically—at least once ever months—a physician specially experienced in the of diabetes mellitus The need for such surveillance emphasised by the importance which insurance com attach to regular medical supervision of diabetic p

Should the initial treatment be in hospital, in a unit, or at home? Two features are essential in treatment (1) the patient must be adequately on diet, urine testing, insulin therapy, and matters, and (2) he should be emphatically told with reasonable care a normal life is attainable For reasons admission to hospital has many und features The routine of hospital life is far remov normality, and mere admission to hospital makes patient feel an invalid Similarly treatment at makes concentrated instruction difficult The with uncomplicated diabetes should be admitted hospital annexe or special convalescent home or so that with the minimum of medical supervision lead a more normal life than is possible in hospital should be able to select his diet from a buffet and instruction, and witness practical demonstrations aspects of routine therapy Such centres could only for initiating therapy, but for routine checks idea is not new, and would have been put into Leeds but for the war The Joslin group are such a scheme at Boston It should save money, the overheads of a hostel would be very than those of a hospital Hospital admission sh reserved for the complicated cases and not utilised routine stabilisation

Conclusion

The most important problem is the development of so called complications, and the evidence suggests the frequency and severity of these depend on duration of the disease and the degree of control essential, therefore, that we should diagnose the earliest possible moment and, once the di made, adopt all means to ensure adequate Sustained adherence to a diet is essential, the given to diet and insulin therapy seems to be the important single factor in good control Adherence diet does not imply starvation No sound yet been forthcoming to refute the contention of (1923) that the most important factor gov sulin requirement with any ordinary plan of diet is ot the carbohydrate content but the total calorie ontent The fact that at least ten years are necessary o assess the effect of a diet on the incidence of complica ions, and that at least 25% of the population have either the inclination to follow a diet nor the intelligence o comprehend what dietary control means should not ause despair The treatment of every diabetic patient an individual affair, and calls for an understanding ot only of diabetes mellitus but of many personal and ocial factors as well as for patience thoroughness in raining and continuity of supervision Finally, good ontrol necessitates attention to the blood sugar level nd the avoidance of hyperglycæmia. The criteria of ood control should be that the patient feels well and is apable of physical activity commensurate with age, that is weight remains steady and is within 10 lb of the ormal for age and height that both ketosis and hypo ycæmia are absent and that the blood-sugar level is ept as near to normal as possible

ANTIBIOTICS IN CHRONIC BRONCHITIS

J ROBERT MAY
M.D Camb.

SENIOR LECTURER IN BACTERIOLOGY INSTITUTE OF DISEASES OF THE CHEST BROMPTON

BACTERIA are often distributed unevenly in the sputum in chronic bronchitis, with the result that single cultures of sputum specimens may fail to reveal all the bacterial species present (May 1952 1953) Cultures should be made from at least five different parts of each specimen or a single culture may be made from liquefied sputum (Rawlins 1953) Using these methods of culture, analysis of the association between pus in the sputum and organisms known to be potential pulmonary patho gens has shown that these organisms especially *Hæmophilus influenzæ* and the pneumococcus, are likely to be pathogens in chronic bronchitis (May 1953) Further evidence for this can be obtained by eradicating the presumed pathogens from the sputum by chemotherapy and noting any coincident improvement in the patient's condition This is the subject of the present report, which includes also some observations on the clinical value of chemotherapy in chronic bronchitis.

Materials and Methods

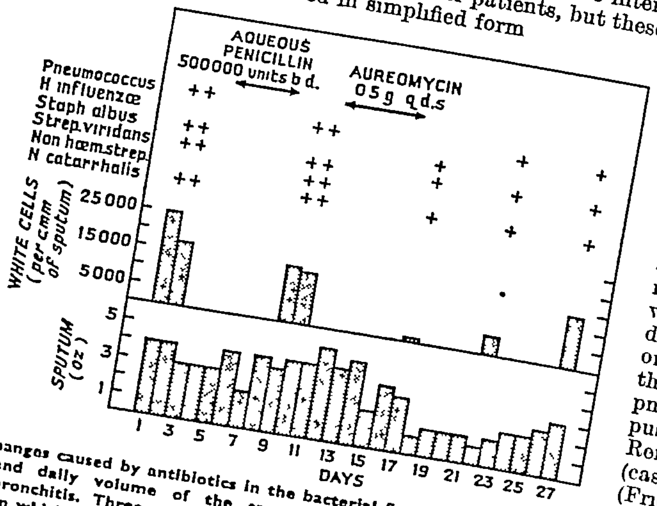
Patients investigated—All the patients investigated were attending the Brompton Hospital There were 18 inpatients, all of whom were expectorating either purulent or mucopurulent sputum and 21 outpatients The sputum of 4 outpatients was either purulent or mucopurulent and that of 17 was persistently mucoid during the period of observation

Collection of sputum—A specimen " of sputum is defined as a portion of sputum produced as a result of one bout of coughing only Specimens for bacteriological examination were expectorated into sterile universal " containers Cultures were made usually within three hours of expectoration of the specimen—never more than six hours. Owing to the variation of flora from one specimen to another (May 1953) at least 6 specimens were examined from each inpatient before and after chemotherapy It was not practicable to obtain more than 3 fresh specimens from outpatients. An interval of two days elapsed in every case between the end of chemotherapy and the examination of further specimens of sputum

Bacteriological techniques—Each specimen was rinsed in about five times its volume of sterile physiological saline solution to remove most of the adherent saliva Cultures were made on blood-agar by either the ' five culture method (May 1953) or a single culture after liquefaction of the sputum by pancreatin (Rawlins 1953) Cultures were incubated aerobically at 37°C for twenty four hours, after which appropriate diagnostic tests were made to identify the organisms isolated

Assessment of changes in patient's condition—Subjective changes in each patient's condition were noted but owing to the difficulty in assessing them, attention was paid mainly to changes in the pus content and to the daily volume of the sputum both of which can be measured with reasonable accuracy In the earlier investigations the proportion of pus was assessed by naked-eye inspection and by examination of stained films of the sputum Subsequently following the demonstration by G A. Rawlins (personal communication) that the cells in sputum were not destroyed by the pancreatin the pus cells were enumerated by a simple counting technique after liquefaction of the sputum The relative numbers of neutrophil and eosinophil polymorphs were determined by differential counts on stained films made from the liquefied sputum White-cell counts were made from time to time in many patients, especially those receiving chloramphenicol ume less ells, and derable When later the pus and the daily creased once more, H *influenzæ* had reappeared in the sputum Though the pneumococcus did not recur, and its exact relationship to the pus could not be assessed, probably this organism and H *influenzæ* were pathogens in this patient

This case has been described in detail to illustrate the use of antibiotics in assessing the significance of organisms in the sputum Similar reasoning was used in the interpretation of changes observed in other patients, but these findings will be presented in simplified form



Changes caused by antibiotics in the bacterial flora pus-cell content and daily volume of the sputum of a patient with chronic bronchitis. Three specimens of sputum were examined for each day on which cultures and counts of pus cells were made. The culture results shown in the chart were compiled by combining the observations made on the three specimens for each day, and the cell counts are the means of the results for each group of three specimens. The lume measurements show the total amount of sputum expectorated each 24-hour period.

TH PURULENT SPUTUM

l 22 patients, all of whom ulent or mucopurulent any clinical evidence of o rise of temperature, and for the incapacity caused organisms isolated from may be considered most

be capable of causing potential pathogens—p *aureus*, group A r's bacillus. These wil

athogenicity as regards *idans*, non hæmolytic *atarrhalis*, and *Staph.* non pathogens."

motherapy was planned in each case to the "pathogens" one by one, but, as explained, this was not always practicable the "non-pathogens" were also noted, but in could the disappearance or reappearance of any organisms be correlated with the presence or pus in the sputum This fact suggests that these were truly non-pathogens

The incidence of "pathogens" in this series is in table I The pneumococcus and H *influenzæ* commonest, hæmolytic streptococci were not The effects produced by eradication of these by chemotherapy were as follows

Pneumococcus

Pneumococci were isolated from the sputum of patients (table I, cases 1–16) They were chemotherapy without interference with the flora in 14 instances In 5 of these the pn was the only "pathogen" In 1 (case 5) th disappeared completely after chemotherapy In 4 (cases 1–4) disappearance of the pneumococ accompanied by disappearance of pus and by in the volume of sputum Pneumococci were with *Staph aureus* in 3 patients (cases 6–8) disappeared from the sputum of 1 (case 6) when organisms were eliminated simultaneously In the 2 other patients (cases 7 and 8) removal of pneumococci was accompanied by disappearance pus, although *Staph aureus* remained in each Removal of pneumococci from the sputum of 7 (cases 9–15) from whom H *influenzæ* was also is (Friedländer's bacillus as well in case 9) led to reduction of the pus in 5 cases and no change in 2 quent removal of H *influenzæ* was accompanied appearance of the pus Simultaneous removal of cocci and H *influenzæ* from 1 patient (case 16) with a reduction in the amount of pus Rel which the reappearance of pus was also reappearance of pneumococci in the sputum observed in 3 patients In 7 others, whose relapse also observed, the "pathogen" was H *influenzæ* lapses were observed in which one or other of these ganisms was not found in the sputum

influenzæ

This organism was found in 14 patients (table I ses 9–22) It was removed from the sputum of 12 ases 10–15 and 17–22) without interference with the maining flora (6 of the patients in whom both *influenzæ* and pneumococci were present were treated st with penicillin to remove the pneumococci the rt played by *H influenzæ* as regards the pus that mained could then be assessed) In each instance the s either disappeared or was very much reduced. In 1 her patient (case 10) *H influenzæ* and a pneumococcus ere eliminated simultaneously with reduction in the nount of pus, whereas in 1 other (case 9) *H influenzæ* d Friedländer s bacillus were eliminated simultaneously, so with coincident disappearance of the pus The ily volume of sputum was reduced in each case when *influenzæ* was eliminated, but in no instance did utum disappear completely Relapses were observed in patients The time of relapse varied from three to elve days after the end of therapy, and in each instance *influenzæ* had reappeared in the sputum In 2 patients e reappearance of the pus preceded the finding of *influenzæ* by two or three days

taph aureus

Staph aureus was found in the sputum of only 3 atients (cases 6–8) and in each instance pneumococci ere also present Eradication of *Staph aureus* and neumococci simultaneously from the sputum of 1 atient was accompanied by disappearance of the pus n the 2 remaining patients the pus disappeared when the neumococci were removed, even though *Staph. aureus* as still present in the sputum

riedländer s Bacillus

Only 1 patient (case 9) was found to be harbouring riedländer s bacilli in his sputum but pneumococci and *influenzæ* were also present. The Friedländer s bacillus uld not be removed from the sputum independently of *influenzæ* and its importance in relation to pus in this atient could not be assessed

PATIENTS WITH MUCOID SPUTUM

Antibiotics were administered to 17 patients who were pectorating only mucoid sputum The patients may be nsidered in 2 groups

(1) Those in whose sputum no ' pathogens could be monstrated (11 patients)

(2) Those whose sputum contained pathogens" (6 tients: 3 with *H influenzæ* 2 with pneumococci and 1 th *Staph aureus*)

Since these were outpatients it was necessary to use antibiotic which could be taken by mouth Chlor phenicol was selected and given in 0 5 g doses three mes a day for five days. The daily volume of the sputum as measured by each patient for three weeks chemo erapy being instituted after the end of the first week ecimens of sputum were examined bacteriologically mediately before, 2 days after and 9 days after emotherapy

In no instance did chloramphenicol cause any alteration the daily volume of the sputum The flora of the utum of patients with no ' pathogens was always e same two days after therapy as it was before In ch of the 6 patients in whom pathogens were found ese organisms were eradicated by chloramphenicol and d not reappear in the following week. Organisms of the sumably non pathogenic group however were still sent in the sputum after therapy So the removal of athogens from patients producing purely mucoid utum apparently does not affect the amount expec rated.

EFFICIENCY OF ANTIBIOTICS

Penicillin was considered to be the antibiotic of choice for the treatment of pneumococcal infections. It was used for this purpose in each of 12 inpatients but not for outpatients, owing to the difficulty of giving regular injections Both aqueous sodium penicillin G and procaine penicillin were used Aqueous penicillin was given in doses of 500,000 units twice daily for five days to 5 patients and for seven days to 3 patients. One patient received 300 000 units of procaine penicillin twice daily for five days, and 3 patients received 600 000 units twice daily for five days. In every case the pneumococci were eradicated from the sputum and there was no need to have recourse to penicillin esters.

The number of relapses of pneumococcal infections after penicillin therapy was difficult to assess, since in many cases *H influenzæ* was also present, necessitating further chemotherapy which may have prevented pneumococcal reinfection Only 3 patients who received penicillin alone could be followed until relapse occurred In 1 the interval was eleven weeks in the 2nd three weeks and in the 3rd two days The sputum remained mucoid in each instance between the end of therapy and the reappearance of pneumococci in the sputum

Streptomycin 1 g twice daily was administered for five days to 5 patients with *H influenzæ* infections. *H influenzæ* was still present in the sputum of 1 patient at the end of the period of treatment It was absent from the other 4 patients sputa. Relapses, in which the reappearance of pus coincided with the reappearance of *H influenzæ* occurred in ten weeks, five days, five days and three days.

Aureomycin 0 5 g every six hours was given for five days to 4 patients with *H influenzæ* infections Neither *H influenzæ* nor the pus disappeared in 3 cases whereas in the 4th patient both *H influenzæ* and pus were removed temporarily The pus reappeared after six days, but *H influenzæ* could not be found in the sputum until two days later One patient who received aureomycin for fourteen days remained free from *H influenzæ* and pus for four weeks.

Chloramphenicol was used more than other antibiotics in the treatment of *H influenzæ* infections because it seemed to be the most efficient agent for the removal of this organism The rapidity with which relapses occurred, however was disappointing and it is doubtful whether the results justify the routine use of this antibiotic in view of the possibility of blood dyscrasias being produced The results obtained with chloramphenicol are shown in table II.

OTHER EFFECTS OF ANTIBIOTICS

In every patient with a purulent sputum in this series some form of chemotherapy eliminated or greatly reduced the pus and usually diminished the quantity of sputum expectorated. Such changes were not necessarily accompanied by subjective improvement in the patients

TABLE II—EFFECT OF CHLORAMPHENICOL ON INFECTIONS ASSOCIATED WITH *H influenzæ*

condition In only 1 patient (table I, case 5) was the expectoration of sputum completely suppressed This patient felt very much better All the other patients, however, were left with a mucoid sputum after chemotherapy, and in many instances this sputum was extremely tenacious and difficult to expectorate These patients complained of increased dyspnœa and were troubled by their unproductive cough In such cases the reappearance of pus and an increase in the volume of sputum was often accompanied by subjective improvement, apparently associated with the loosening of bronchial secretions Unfortunately no means were apparent whereby it could be predicted before therapy which patients were likely to respond in this way

The rapidity with which the sputum returned to its former state after chemotherapy has already been described In 6 patients the reappearance of pus in the sputum was associated with clinical evidence of acute bronchitis In 5 cases three or more antibiotics had previously been administered, the 6th patient had received only one antibiotic

Discussion

In an earlier communication (May 1953) the organisms known to be able to cause acute pulmonary infections (potential pathogens) were shown to occur significantly more often in purulent than in mucoid sputa in chronic bronchitis This suggested that one or more members of the group could cause infections in this condition as well as in acute pulmonary disease The present investigations were undertaken to test this hypothesis further, and the results are in complete accord with the earlier findings Two organisms, *H influenzæ* and the pneumococcus, seem to be far more important than any others in chronic bronchitis

It may be argued that the therapeutic test has only a limited value in this type of disease There is always the possibility that an antibiotic may have effects other than the elimination of recognisable bacteria, and that improvements observed in the patient's condition do not necessarily result from removal of these organisms This, of course, is true, but the repeated observation of the disappearance of pus when *H influenzæ* and pneumococci are eradicated from the sputum, together with the reappearance of pus when they return, makes the probability of cause and effect a strong one The number of patients studied was small, but the results seem likely to be significant since they confirm the observations of Mulder et al (1952) and Stuart Harris et al (1953), who reported on the importance in chronic bronchitis of *H influenzæ* and the pneumococcus respectively

The part played by bacterial infection in the pathogenesis of the clinical state customarily referred to as chronic bronchitis has not been assessed in these investigations In most patients chemotherapy seems able only to render a purulent sputum mucoid, and patients with mucoid sputum apparently do not benefit from antibacterial treatment This suggests that, in established chronic bronchitis, bacterial infection is a secondary phenomenon Its importance as a cause of the hypersecretion of mucus, which is apparently of fundamental importance in chronic bronchitis (Oswald et al 1953, Reid), has not been assessed, nor has any attempt been made to define the rôle of viruses Stuart-Harris et al (1953), who investigated the association between influenza virus infection and bronchitis, found that this association was most frequent during acute exacerbations These have not been studied in detail in the present investigations

The organisms of doubtful pathogenicity in the lungs, especially *Strep viridans*, non-hæmolytic streptococci, and *N catarrhalis*, are found almost universally in both purulent and mucoid sputa The fact that their incidence is the same in the sputa and throats of the same patients (May 1953) suggests that they represent simply a extension of the flora of the upper respiratory tract a bronchial tree sufficiently damaged to be unable dispose of them efficiently It is possible, of course, these organisms are really only contaminants from mouth and are added to the sputum as it is expector This is unlikely, however, since in this investigation was found that they were still present in large in pieces of mucoid sputum which had been very washed to remove any adherent saliva

The evidence, then, from bacteriological and therapeutic studies suggests that in chronic the mucus in the affected parts of the bronchial colonised more or less evenly by organisms from upper respiratory tract, most of which are non If infection takes place, as manifested by the pro of pus, it is usually caused by *H influenzæ* or by pneumococcus These organisms are often distributed in the sputum, and possibly this irre reflects a patchy distribution of infection in the chial tree The histological observations of confirm the hypothesis that the infected areas irregularly scattered throughout the lungs and not necessarily coincide with the sites of mucus

Though these investigations were not planned to assess the place of antibiotics in the treatment chronic bronchitis, certain observations have been which seem to bear directly on this matter (1) patients feel worse rather than better after chemoth owing to the difficulty in expectorating their tenacious mucoid sputum, and (2) the rel especially of *H influenzæ* infections, is high, and in cases the reappearance of pus in the sputum is panied by fever and malaise Though many undoubtedly feel much better for some time after therapy, these disadvantages should strike a n caution about the indiscriminate use of anti chronic bronchitis

Summary

The significance of organisms in relation to pus sputum in chronic bronchitis has been inv by determining the changes in the sputum brought by antibiotics

Two organisms, *Hæmophilus influenzæ* and pneumococcus, seem to be far more important than others in chronic bronchitis

Purulent sputum can be rendered mucoid and diminished in quantity by suitable chemotherapy in most patients relapses, especially of *H* in infections, occur rapidly after the discon treatment These relapses may be accompanied by and malaise

Patients expectorating only mucoid sputum do seem to benefit by chemotherapy, no matter bacteria are present

The change from purulent to mucoid sputum b about by chemotherapy makes some patients feel than they did before therapy This is due to the viscidity of their mucoid secretions, which are h to expectorate and cause increased dyspnœa

I wish to thank Dr Neville Oswald for his unfailing agement and coöperation and for permission to inve his patients, and Mr G A Rawlins for his invaluable tec assistance

POSTGRADUATE SCHOOL OF LONDON HAMMERSMITH HOSPITAL

THE seriousness of the effects of chronic bronchitis, pecially in middle aged and elderly men in our large ndustrial towns, is emphasised by Goodman et al 1953) Chronic bronchitis causes not only many deaths ut also a serious loss of working time

Although many of the patients remain relatively well luring the summer they cannot obtain continuous mployment because they become much more seriously lisabled when autumn arrives In autumn and winter heir sputum becomes more profuse and purulent and heir dyspnœa increases. The cause of these acute xacerbations is little understood. Stuart Harris et al 1953) found no significant difference between the acterial flora of the sputum in exacerbation and that n "relative quiescence but they do not state whether oth groups had purulent sputum or whether the uiescent cases had only mucoid sputum It would be urprising if the development of purulent from mucoid putum were not associated with at least a quantitative hange in the bacterial flora Stuart Harris et al also ound that the bacterial flora closely resembled that ound in the upper respiratory tract of healthy people, nd conclude that 'in chronic bronchitics there is essen lally a failure of defence of the lower respiratory tract gainst invasion by nasopharyngeal organisms,' which hey attribute to preceding infections

The autumn exacerbations are probably due to further amage to the epithelium of the lower respiratory tract y virus infections or by atmospheric irritants which reate conditions favouring proliferation of organisms om the upper respiratory tract Little can be done to revent these predisposing injuries but if the subse uent bacterial proliferation were controlled by anti otics, the severity and duration of the acute exacerba ons might be reduced. To achieve this it would be cessary either to administer the antibiotic continuously roughout the winter or to start giving it at the first mptom of each exacerbation Either of these methods at especially the former would carry the risk of acquired cterial resistance to antibiotics.

A preliminary study of the changes in the bacterial ora of chronic bronchitic sputum produced by various antibiotics and the development of resistance was made on a small group of bronchitics who received courses of penicillin chloramphenicol aureomycin and sulphadimidine

MATERIAL

Since many specimens of sputum were required, 13 patients with chronic bronchitis were selected from the outpatients of Hammersmith Hospital who because of the severity of their bronchitis were unemployed and could attend daily without financial loss. They attended a weekly clinic and brought specimens of sputum to the bacteriological department on intervening days At the clinic the severity of their exertion dyspnœa was estimated according to five grades of severity (Fletcher 1952) A note was made of subjective changes in dyspnœa cough, and sputum Details of the patients are given in table I

Courses of Treatment

The 13 patients received between them twenty four courses of treatment between October 1952 and March 1953 (table I)

Penicillin was given orally in seven-day courses during which 200 000 units was given four hourly during the day (five doses) making 1 000 000 units in each twenty four hours Three of the courses were given without any antibiotic therapy having been given in the preceding three months Courses were also given to 3 patients who had each had a course of chloramphenicol six weeks previously (2 of these had each had also a course of penicillin six weeks before the chloramphenicol) and to 2 patients who had had a course of aureomycin six weeks previously In these cases the bacterial flora appeared to have regained its pretreatment status before the penicillin was given. Oral penicillin was used because we considered that parenteral administration would be impracticable for prophylactic purposes. We feared that larger doses would give rise to severe gastro intestinal disturbances In 3 cases we found a serum penicillin level higher than 1 unit per ml two hours after the last dose

Chloramphenicol was given in seven-day courses of 500 mg four times daily to 4 patients 2 of these had had oral penicillin six weeks previously and their bacterial flora had regained its pre treatment status

Aureomycin was given in seven-day courses of 500 mg four times daily to 5 patients, of whom 2 had a second five-day course of the same dose 5-9 weeks later when their bacterial flora had regained its previous status.

Sulphadimidine was given in seven-day courses of 1 g four times daily to 4 patients who had had no preceding treatment

Methods

Bacteriological

Specimens of sputum coughed up during the first two hours after waking were examined twice before treatment, daily during treatment, on alternate days during the next week, and thereafter at longer intervals.

TABLE I—DETAILS OF CASES

Case	Age (yr)	Sex	Grade of dyspnœa	Amount of sputum	Length of history of bronchitis (yr)	Courses of treatment		
						1st	2nd	3rd
1	66	M	4	+ +	35	Aureomycin 7 days	Aureomycin 5 days	Penicillin
2	61	M	4	+ +	20	Aureomycin 7 days	Aureomycin 5 days	Penicillin
3	66	M	3	+	15	Penicillin	Chloramphenicol	Penicillin
4	68	M	3	+	12	Penicillin	Chloramphenicol	Penicillin
5	60	M	3	+	7	Chloramphenicol	Penicillin	
6	53	M	4	+	14	Chloramphenicol	Penicillin	
7	63	M	4	+ +	30	Sulphadimidine	Aureomycin	
8	42	F	3	+	8	Aureomycin 7 days		
9	63	M	4	+ +	00	Aureomycin 7 days		
10	56	M	4	+	25	Sulphadimidine		
11	46	M	3	+ +	6	Sulphadimidine		
12	63	M	4	+ +	4	Sulphadimidine		
13	68	M	3	+	35	Penicillin		

The method of examination was as follows

5 ml of sputum was washed in a saturated solution of sodium chloride to minimise salivary contamination, and next added to 5 ml of physiological saline solution and homogenised by mechanical shaking for an hour at 37°C in bottles containing glass beads This homogenisation was done in view of the heterogeneous distribution of organisms in sputum (May 1952) Duplicated samples of 30 sputa homogenised by this method were found to contain the same organisms in the same relative proportions

From this suspension viable counts by Mitchison's (1953) method, cultures on blood agar medium, and "gutter plate" sensitivity tests were set up with a standard loop The plates used for sulphonamide sensitivity tests contained 5% laked horse blood The gutters contained penicillin 10 units per ml, aureomycin 25 µg per ml, chloramphenicol 50 µg per ml, and sulphadimidine 10 mg per ml A test on a control sensitive organism (*Neisseria catarrhalis* for sulphadimidine, *Staphylococcus aureus* for the remaining antibiotics) was included on each plate Further aureomycin sensitivity tests were made by inoculating colonies on to agar plates containing 1, 2, 4, 6, 8, and 10 µg per ml

The plates were examined after eighteen hours' incubation at 37°C The organisms were identified and their total number, relative proportions, and antibiotic sensitivity recorded

Microscopic

Two smears of each specimen were examined They were made from the thickest area of sputum before it was washed, were fixed wet in Carnoy's fluid for a minute, and stained with pyronine methyl-green (Brachet 1942) and 0 5% toluidine blue in pH 4 5 buffer Both were stained for twelve hours, dehydrated quickly in two changes of tertiary butanol, and mounted in D P X These preparations were especially suitable for examination in polarised light to show up the extracellular structure of the sputum, and were analysed in a similar manner to that described by Elmes and White (1953) Viscidity was not measured

The following characteristics of each specimen were recorded total cellularity, profusion of polymorphs, mononuclear inflammatory cells, epithelial squames, clumps of bacteria, dust cells, and Curshman's spir and density of mucoprotein fibre network and deoxyribonucleoprotein fibres

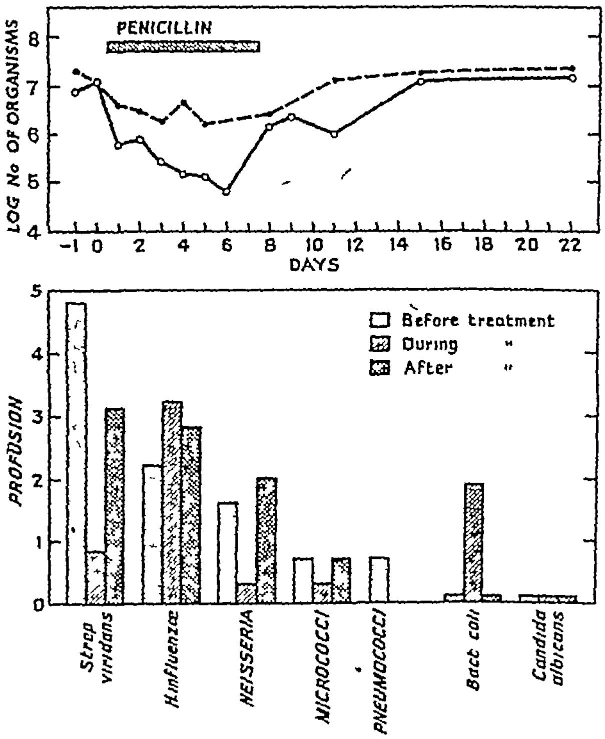

Fig 1—Average effect of penicillin on total bacterial count (above) and on relative profusion of individual organisms (below) open circles first course solid circles second course

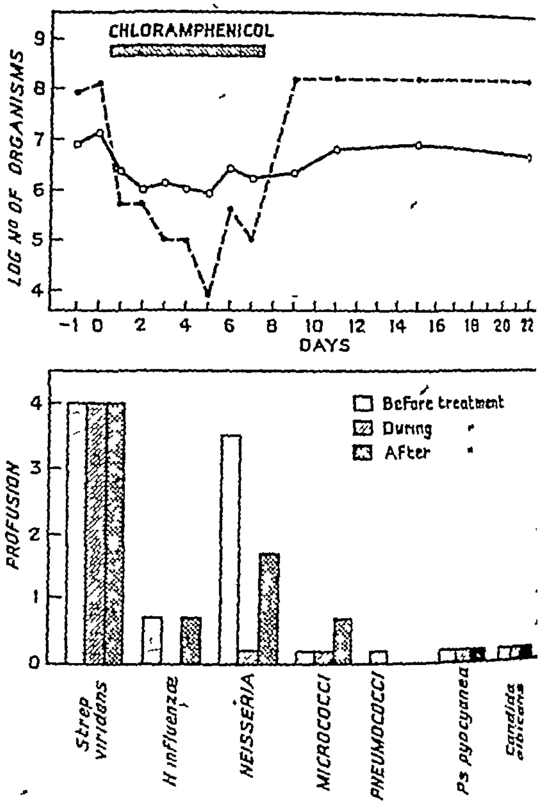

Fig 2—Average effect of chloramphenicol on total bacterial co (above) and on relative profusion of individual organisms (bel open circles, average of 3 patients, solid circles, case 4.

Areas in the smears showing bacterial clumps and epithelial squames were taken to originate from sal and were ignored in the cellular and fibre estimat The mucoprotein was distinguished from the deox ribonucleoprotein in the films stained with pyron methyl green by the sign of birefringence with a ¼ compensator The mucoprotein showed positive a birefringence, and the nucleoprotein fibres negativ axial birefringence

Results

Flora

In the pre treatment specimens *Streptococcus virid* was most frequently the predominant organism (11 of 13 patients) *Neisseria pharyngis* was present in patients, and *Hæmophilus influenzæ* in 8 Micro were present in 8 patients but only in scanty num *Strep pneumoniæ* was isolated from 2 patients, be predominant in 1 of these *Candida albicans* was iso from 4 patients, but in each it formed only a proportion of the whole flora

During treatment a decrease in the total numb viable organisms and an alteration in the proport of different organisms in the flora were noted.

To illustrate our findings we have combined the of all courses of treatment by each drug This see justified since all the responses were closely sim except that which followed one course of chlor phenicol This is illustrated separately The total co are expressed as the average logarithm of the of organisms per ml The changes during treatment shown graphically in figs 1–4 The relative pr of the organisms are expressed as the average of arbi values (profuse growth = 5, moderate growth = scanty growth = 1) This average value of each or fore during, and after treatment is shown by stograms

ffect of Penicillin

Fig 1 shows the effect of penicillin in the nine courses treatment The total number of organisms was duced but returned to the pre treatment level a week ter treatment A second course of treatment given 2 patients three months later produced a similar but ss pronounced effect The relative proportion of the ganisms was altered during treatment Among the nicillin sensitive organisms *Strep pneumoniæ* present 1 patient, disappeared completely *Strep viridans* as greatly reduced in number and there were fewer eisseriæ and micrococci No acquired resistance to enicillin was found Among the penicillin resistant rganisms *H influenzæ* initially present in 7 patients ecame the predominant organism in all except 1 *acterium coli* appeared for the first time in 6 patients nd *Pseudomonas pyocyanea* in 1 The number of *albicans* present in 1 patient, was unaffected

After treatment *H influenzæ* remained the predominant rganism for at least three or four weeks *Ps pyocyanea* emained present in small numbers and *Bact coli* isappeared within fourteen days. The penicillin sensitive rganisms returned to their pre treatment state within ourteen days

ffect of Chloramphenicol

Fig 2 shows the average effect of chloramphenicol iven to 4 patients The reduction in the total count was light in 3 patients but pronounced in the remaining atient owing to the disappearance of *H influenzæ* hich had been profuse The neisseriæ were reduced, nd the *Strep pneumoniæ* present in 1 patient dis ppeared. The remaining organisms were unaffected. fter treatment *H influenzæ* returned in profusion two ays after the cessation of treatment No acquired resistance to chloramphenicol was noted

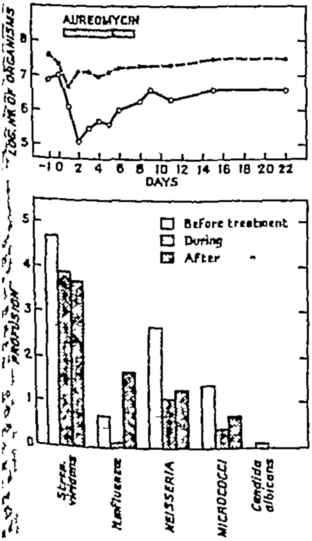

Fig 3—Average effect of aureomycin on total bacterial count (above) and on relative profusion of individual organisms (below): open circles first course; solid circles second course

Effect of Aureomycin

Fig 3 shows the effect of aureomycin in seven courses of treatment The reduction in the total count was considerable in the patients receiving the drug for the first time owing to a decrease in the number of all the organisms A second course of treatment given to 2 patients one and two months later had a similar but less pronounced effect

In all the patients the minimal inhibitory concentration of aureomycin for strains of *Strep viridans* isolated before treatment was 2 or 4 µg per ml that for strains isolated three days after the start of treatment was 6 µg per ml; and that for strains isolated four days later was 10 µg per ml Resistance remained after two months and was slightly increased when a second course of treatment was given *H influenzæ* and micrococci showed no acquired resistance The strains of *Strep viridans* from all the patients had become sensitive again two months after the second course of treatment

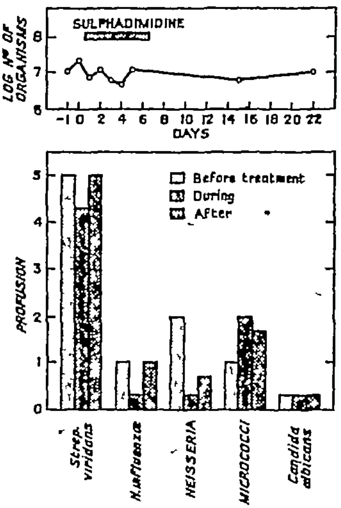

Fig 4—Average effect of sulphadimidine on total bacterial count (above) and on relative profusion of organisms (below)

Effect of Sulphadimidine

Fig 4 shows the average effect of sulphadimidine given to 4 patients. The reduction in the total count was slight in all the patients and was due to a reduction in the numbers of *Strep viridans H influenzæ* and the neisseriæ

Microscopy

In all the patients polymorphs were present in considerable numbers before treatment was started, although in some the sputum was macroscopically mucoid. This probably indicates persistent active inflammation of some part of the bronchial tract During exacerbations of symptoms there was a tendency for polymorphs and fibrous nucleoprotein to increase and for the sputum to become purulent Thus our findings confirm those of Elmes and White (1953) That this should happen with the appearance of a pneumococcus or *H influenzæ* is not surprising but it also happened in exacerbations which seemed to be due to ' colds or to fog without the emergence of any generally recognised pathogen in the flora of the sputum

To study these causes of bronchial inflammation more quantitatively the sputa were classified according to the microscopical findings into purulent and non purulent specimens. In table II the frequency of the two types in all the specimens is related to the presence of moderate or profuse growth of *Strep pneumoniæ* and *H influenzæ* and to the incidence of fog during the preceding three days It will be seen that there is a significant association between purulent sputum and significant growth of *H influenzæ* Only 2 patients had *Strep pneumoniæ* hence there were too few specimens to show any association with purulence The association with fog was suggestive but not significant. In the absence of any of these influences the sputum was significantly less often purulent

TABLE III—EFFECT OF FOG ON SPUTUM

H influenzæ	Fog	No of sputa showing purulence graded as					Total	P
		—	±	+	++	+++		
Absent	Present	5 (6 7%)	30 (40%)	19 (25 4%)	18 (24%)	3 (4%)	75	0 7–0 5
	Absent	9 (6 5%)	63 (43 4%)	47 (32 4%)	21 (14 5%)	5 (3 4%)	145	
Present	Present	0	6 (11 8%)	11 (21 6%)	23 (45%)	11 (21 6%)	51	0·02–0·01
	Absent	0	11 (12·2%)	36 (40%)	38 (42 2%)	5 (5 6%)	90	

P was determined by χ^2

To study further the effect of fog the cases were divided into those with and those without any growth of *H influenzæ* in foggy and non-foggy weather (table III) This showed that fog had a significant effect in increasing the purulence of the sputum only in patients with *H influenzæ* in their sputum

During periods of treatment it was found that, when the total bacterial count was reduced for more than three days, or when *Strep pneumoniæ* or *H influenzæ* disappeared, the sputum became mucoid and polymorphs were scanty Bacteriological relapse was followed by a return to the status quo ante When the treatment was bacteriologically ineffective, there was no change in the microscopical characteristics of the sputum

Clinical Results

Since our chief interest was in the effects of the drugs on the bacteriological flora of the sputum, the courses of treatment were guided by these findings rather than by clinical indications, except in 1 patient who had a severe exacerbation requiring admission to hospital, when he was treated successfully with oral penicillin

TABLE II—CLASSIFICATION OF SPUTA

Cause of inflammation	No of purulent sputa	No of non purulent sputa	P
*Strep pneumoniæ**	3	3	<0 001
*H influenzæ**	62	42	0 1–0 05
Fog	52	74	<0 001
Remainder	32	128	
Total	125	236	

* Present in moderate or profuse numbers

P was determined by χ^2, the distribution of each group being separately tested against the total remaining

With this exception the clinical effects of the courses of treatment were not striking In a third of the cases the courses appeared to give some relief of dyspnœa and cough, but this response was no more than might have been achieved by a placebo A properly controlled trial with objective assessment of pulmonary function would be necessary to show whether or not short courses of antibiotic treatment do any good in chronic bronchitis except during acute exacerbations

Aureomycin caused diarrhœa in four of the seven courses, chloromycetin in two out of four, and penicillin in one out of nine

Conclusions

Penicillin, in the dose that we used, was effective against most of the bacteria in the sputum, but it allowed, or even encouraged, the emergence of *H influenzæ* as a dominant organism, and this we found to be associated with increase in the purulence of the sputum, especially during foggy weather It would therefore be unwise to use penicillin for continuous prophylaxis throughout the winter, and it has been shown by Kuh and Collen (1949) that such administration has little effect on the incidence of respiratory infection in large groups of the general population Penicillin might be suitable for administration intermittently at the onset of any acute exacerbation It would probably be effective in the dose we used xacerbations due to *Strep pneumoniæ*, but to protect against exacerbations due to *H influenzæ* large parenteral doses perhaps combined with streptomycin (Mulder et al 1952) would be required, which would scarcely be practicable except on a very limited scale

Chloramphenicol had a surprisingly small effect on the general bacterial flora It was effective against *H influenzæ* and might be most useful, but the danger of agranulocytosis following its repeated or prolonged use renders it unsuitable for prophylaxis

Aureomycin was the most effective of the drugs against the whole bacterial flora but it produced resistance in *Strep viridans* and a second course, while resistant strains were still present, proved less effective than the first Thus it appears unsuitable for prophylactic use either continuously or intermittently

Sulphadimidine had very little effect on the general bacterial flora Continuous administration in small doses throughout the winter has no prophylactic effect against winter exacerbation of bronchitis in cases of pneumoconiosis (Kilpatrick 1953) Larger doses could hardly be used without risk of toxic effects Intermittent administration might well be of value against exacerbation due to *Strep pneumoniæ*, but, until we know the frequency with which this organism rather than *H influenzæ* and the other denizens of the sputum is responsible for the exacerbations, we cannot forecast how useful it would be

Our conclusion is that none of the drugs we used would be suitable for prophylaxis of acute exacerbations of chronic bronchitis The requirements of a drug for this purpose are that it should be cheap, free from toxic effects, effective against the whole range of bacteria responsible for chronic bronchitis, and not likely to impart acquired resistance If and when such a drug becomes available, an enormous amount of disability in men of working age might be prevented

Summary

A small group of patients with chronic bronchitis were given short courses of penicillin, aureomycin, chloramphenicol, and sulphadimidine

The bacteriological and microscopical changes in the sputum and the clinical effects were observed Although each drug, except sulphadimidine, temporarily reduced the bacterial counts and the purulence of the sputum, the clinical effects were slight

For various reasons none of the drugs appeared suitable for the prophylaxis of acute exacerbations.

Foggy weather appeared to have a more deleterious effect on cases with *H influenzæ* in the sputum

We are indebted to Prof Lord Stamp and Dr D Mitchison for advice and criticism

ACUTE adrenal failure in meningococcal septicæmia s been treated successfully by Grace et al (1940) with racts of suprarenal cortex by Banks and McCartney 43) with 'Eucortone' by Nelson and Goldstein 51) with intramuscular cortisone by Newman 51) with intravenous cortisone in patients whose nditions had deteriorated in spite of treatment with ract of adrenal cortex; and by Magnus (1953) th intravenous eucortone and deoxycortone acetate ccessively

We report here two cases in which eucortone and rtisone were given concurrently, with recovery of both tients

Case-records

Case 1 —A healthy schoolboy aged 15 had prodromal laise and lassitude for twenty four hours, followed by ffness of his legs and back He was found lying on his bed ghtly confused and with a temperature of 100°F at 10 P.M 10.30 P.M. he was examined by the school doctor who found neralised muscular weakness a weak rapid pulse and a techial rash. Lumbar puncture produced clear cerebrospinal id (C.S.F) under normal pressure and containing no organ ms or cells. At midnight the boy was seen by one of us M. B.) he was then extremely prostrated with systolic od pressure 50 mm. Hg (diastolic unobtainable) conjunc al suffusion and subconjunctival hæmorrhage faucial ection a rapidly spreading petechial rash and muscle derness There were no signs of meningitis. Meningococcal ticæmia was diagnosed provisionally and the patient was en intramuscular penicillin 1 mega unit and intravenous phadimidine 3 g

On admission to hospital at 1 30 A.M. next day he was fused but able to drink. Tachypnœa and tachycardia re severe Despite a blood pressure of 65/40 mm Hg and weak pulse his skin was warm and flushed, and peripheral nosis was present producing a purple lividity of nail beds, , cheeks and ears. The petechial rash was mainly distri ted over the distal parts of the limbs with only scanty ions on the trunk.

Treatment —Eucortone 10 ml and cortisone 100 mg were en intramuscularly on admission. At 4 A M intravenous ortone 20 ml was given At 5 A.M. a 5% glucose saline usion of 20 oz. was started and intravenous sulphadimidine was given. At 6 A.M intravenous eucortone 20 ml was n and a plasma infusion was started. Though he was still scious, with pronounced hypotension the patient was lious and could no longer coöperate Oxygen therapy by sk was attempted. At 9 30 A.M restlessness and delirium re extreme and peripheral lividity was still present but blood pressure was unrecordable The restlessness and rosis decreased when the boy was put in an oxygen tent ger's solution was substituted for plasma. Intramuscular tisone 100 mg was given and a course of intravenous rtone 10 ml. two hourly was started At 1 P.M a slow sion of plasma was begun Intravenous sulphadimidine and intramuscular penicillin 500 000 units eight-hourly given At 10 P.M the pulse-rate was 130 and blood ssure 70/40 mm. Hg Glucose drinks were taken in small ntities.

Third Day.—At 4 A.M Ringer's solution was substituted for ma because the levels of serum and urinary chlorides were porarily below normal though the blood sugar level had ained normal At 9 A.M the pulse rate was 110 and blood ssure 75/15 mm. Hg The dose of intravenous eucortone changed to 10 ml four hourly At 4 P.M., since there was evidence of overloading of the circulation and mouth feeding was practicable intravenous infusions were stopped The total urinary volume since admission was 73 oz. The serum potassium level had fallen to 12 mg per 100 ml. (3 1 m.eq per litre) This deficiency was corrected by giving potassium chloride 2 g daily by mouth for three days Intramuscular eucortone 10 ml was now being given four hourly and the dosage of sulphadimidine was changed to 1 5 g eight hourly by mouth and of penicillin to 500 000 units b d At 10 P M the patient was comfortable with pulse-rate 100 and blood pressure 85/50 mm Hg A course of cortisone 25 mg by mouth was started

Fourth Day —Cortisone 12 5 mg was given by mouth every six hours, and intramuscular eucortone 10 ml four hourly Penicillin and sulphadimidine therapy was continued

Fifth Day —The patient began to take solid food and his blood pressure remained steady Eucortone therapy was discontinued

Further Progress —The dosage of cortisone was reduced to 25 mg on the seventh and eighth days, and to 12 5 mg on the succeeding four days The total oral dosage was 275 mg in eleven days. Throat, nose, and skin cultures, taken on the day after chemotherapy had been started were sterile Oliguria did not develop; proteinuria and reduced urinary secretion of chloride were transitory The only electrolyte disturbance was a temporary fall in the serum potassium and plasma-chloride levels on the third day the blood sugar level remained normal The patient was discharged fit after twenty eight days with a blood pressure of 125/65 mm Hg

TABLE I—FLUID BALANCE BLOOD UREA LEVELS, BLOOD PRESSURE, AND DOSAGES OF EUCORTONE AND CORTISONE IN FIRST SIX DAYS OF TREATMENT OF CASE 1

Days	2	3	4	5	6	7

Intramuscular	10	20	60	30	—	—
Cortisone (*mg*):						
Intramuscular	200	—	—	—	—	—
Oral	—	25	50	50	50	25

Fluid balance, blood urea levels, blood pressure, and intake of eucortone and cortisone in the first week of treatment of case 1 are shown in table I

Case 2 —A cretin aged 45 who had been treated from the age of 3 years with thyroid extract complained of sudden feverishness, vomiting headache backache and, later in the day abdominal pain.

On admission to hospital at 10 P.M. on the second day of illness he was mentally alert pale cyanosed, and sweating with an extensive purpuric rash and neck rigidity

Investigations —Lumbar puncture produced turbid C.S.F under increased pressure and containing polymorphs and gram negative diplococci. The blood pressure was 130/70 mm. Hg

Treatment —Intravenous and oral sulphadiazine and intrathecal penicillin were given
